INDEX TO VOLUME I, FOR 1938

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate headings—for example, Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Child and Infant; Goitre, and Thyroid. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Annotations," "Correspondence," "Leading Articles," "Obituary," "Reviews," etc. Original Articles are indicated by the letter (O).

A

- ALICE-Anderson, Sir Maxine, obituary notice of, 1.
 ALB, W. N.: See *Synopsis of work*, 112.
 ALB, John Jacob: Elected Foreign Member of Royal Society, 1166.—Obituary notice of, 1166.
 ALBERTOWSKI, R. G.: Pathology of adolescent scoliosis, 215 (O).—Leading article on, 216a.—Trauma and progressive muscular atrophy, 559.
 ALBRITTON, Alexander, review of his book, 731.
 ALCOHOL: Analysis of 250 cases of (R. G. Cooke), 1043 (O).
 —law relating to, discussion on, 108.—Correspondence on, 541.
 —associated with brain filament cysts and *B. volutans* infection (R. Butterfield), 173.
 ALLEGRA, Adolfo: Influence of alcohol, tobacco, and physical therapy, 569.
 ALLEN, A. and ALLEN, R. (J. McNellie, Eds.):—
 ALVAREZ, acute epidural (W. R. D. Mitchell), 1149 (O).
 —retrolental and quincy (R. Scott Stevenson), 1123.
 ART, A. A.: 1937 Year Book of Pediatrics, 575.
 ALEXANDER, Italian army in, 805.—Health of refugees (Parliamentary Notes), 577.
 ARMED Forces of Medicine: New President, 656.
 ARTERIO-SCLEROSIS:—
 Status of Hypertensive untreated, 456.—Optic atrophy, 641.—Control of sera and vaccines by, 642.—Link to, 1223.—Hereditary factor in high blood pressure, 1219.
 ACADEMY OF MEDICINE IN IRELAND, ROYAL:—
 Hygiene and diet, 635.
 —Meeting of, 129.—Tomography, 668.—Buzzle branch block, 655.—Cataracts and conjunctival diphtheria, 1172.—Braun-Paul pulsatron in treatment of respiratory paralysis, 1206.
 Section of Pathology.—Meetings of, 556, 914.
 Section of Surgery.—Surgery and dental clinic, 959.
 ACADEMY, International, of Postgraduate Medicine, 1120.—Address of, 1252.
 ACCIDENTS, prevention of: Congress of National Safety First Association, 1221.
 —road, and ill-health, 1216.
 —road, No. of, at crossings where traffic lights operate, 577.
 ACETYLCHOLINE, clinical aspects of transmission of effects of nervous impulses by (Francis R. Frazer), 1249 (O), 1257 (O), 1249 (O).—Leading article on, 1170.—Correspondence on, 1233.
 —altered effect on immobilized joints (A. M. Harvey), 825 (O).
 —action of, 129.
 ACID-BASE equilibrium, 556, 648, 657, 1232.—Annotation on, 537.
 ACHROMYCETES caprae, human infection with (A. G. Gibson and others), 612 (O).
 ACTINOMYCETOSIS, review of book on, 1096.
 ADAMS, F. L.: Maternal Care, revt., 353.
 ADAM, C. (and R. ACLE): Severe Epiglottitis and its treatment, 1121.
 ADAMS, W. C.:—
 Psychiatric Prev., 124.
 —Adams, W., called to the Bar, 219.
 ADDICTION, prevention and control of, 155.
 ADLER, Alfred, and psychological medicine: relation of sexes, 20.—His contribution to general medicine, 475.
 ADOLESCENT, review of book on, 1211.
 ADONIS, East: Tuberculosis in Tanzania, 1107.—
 —Malaria and mental health in Kenya, 1573.
 —South: Nutrition of natives (Parliamentary note), 547.—Typhoid fever on the Witwatersrand, 1109.—Annual report of health department, 1221.—
 —Appointment of Secretary for Public Health, 1273.
 AFRICA, South, Medical Journal, issues devoted to, 1245b, 23.
 AGITA, Euterpe: Pasteurization of milk, 754.
 AGRANULOCYTOSIS, review of book on, 1097.
 AIR FORCE: See Services.

AIR HAND UTICATIONS

- Appliances in, 478
 Government officers and, 1153
Hot Pool, No. 2, 1015
 Hospitals and, 161, 202, 760, 924, 1031, 1282, 1400
 In Northern Ireland, 1122
 Model universities, 1127
 Municipal work in representative of, 1112, 1011
 Organization of medical services, 910—Antisocial in, 1011
 Sanitation in municipal, 1601
 Sanitary regulations, 957
 AITKEN, R. Value of atropine and hyoscine, 537
 — R. S. Mineral salts in therapy, 531
 ALABASTER, George, H. : Contra-reactions and tests, 410, 529
 ALFLEY, A. : Having antithesis, 857
 ALPERT, I. : General factors in rheumatism, 525
 ALPERT, and Leitch, 436
 ALPERT, and Leitch, 436
 — Infection, intra-uterine, for relief of pain (Clemence Ottley), 510 (0)
 — — — for the toxic leucoplasia, 560
 — — — No. of changes of drunk while in charge of car, 825
 — — — Infection, and physical efficiency, 850
 Allotment, review of book on, 176
 Allerton, Squadron Leader Ronald Eberhard, of honorary notice of, 491
 ALEXANDER, F. : Death from warping, 1348
 — John : *Cystic Therapy of Pulmonary Tuberculosis*, 1212
 — Mineral content of brain, 457
 Allingham, and Bryant, both of (H. Gordon Thompson), 7 (0)—Correspondence on, 201
 — tract, review of book on, 176
 ALLEN, F. J. : Operation to restore opposition of thumb, 1365
 — F. M. B. : Distal polio in child, recovery
 Allergy, drug (leading article), 269—Correspondence, on, 454, 591
 — experimental, 1226
 — review of book on, 451
 ALLISON, P. R. : Healing of empyema cavities, with special reference to aspiration and air replacement at all operation, 272 (0)
 — — — Spread of tuberculous infection, 866
 ALLOTT, E. N. : Mineral salts in therapy, 532
 ALPERT, treatment of, 104, 1247
 ALSTED, Stanley : *Painless Textbook of Pharmacology and Therapeutics*, second edition, rev., 1314
 Altmeyer, Hans, death of, 926
 Altmeyer, Hans, death, 1331
 — Instruction, elementary, 1192
 Amersbach : Its aetiology and treatment (T. N. MacIntosh), 717 (0)
American Heart Journal : Change of editor, 537, 1317
 American medicine, review of book on, 266
 Ammanford colliery, investigation at (parliamentary order), 82
 ANON. : Health of coal miners, 476
 Anaemia, hypochromic, in infancy, 554
 Anaemia and tropical diseases, 554
 Anaesthesia, work, for insertion of radium to epithelioma of lip (Phyllis F. L. Daplyn), 512
 — distal ether, 1026, 1127, 1175, 1237—Drip feed for
 — — — nasal endotracheal, tumour of vocal cord following (Michael Cohen), 283—Correspondence on, 1127
 — — — for (ophthalmic operations, discussion on, 1015
 — risks of explosion in (leading article), 456
 — spinal, changes in blood pressure and respiration following (H. L. Lewis and E. G. M. Palmer), 1292 (0)
 — — — Why "post-anesthetic" pulmonary complications? (G. K. Osborn), 573 (0)—Correspondence on, 457, 1127
 Anaesthetic, new local (leading article), 825
 Anaesthesia at 6
 Analysis, quail
 — Diet: 1265
 Anaphylaxis, review of book on, 125

Anatomy, review of book on, 124, 285, 306, 732

- ANDERSON, C. S. : Bacteriological carcinoma, 57
 — J. Barents et al.: Vladimir B. defficiency, 414
 — Robert-God. John, of literary notes of, 1241
 — Hallett : Time for railway, 420, 595
 Andrews, Charles Horace, of literary notes of, 515
 Ankers, advertisements, of railway notes, disc-
 cussed in, 1011
 — secondary, of left common iliac artery (D. P.
 Rankin), 1051
 Archives of : — clinical study (Geoffrey Scott) and
 R. Bailey Smith, 55 (40)
 Arteriospasm and head injuries, 213
 Arterio, Henry, of literary notes of, 499
 Arterio, review of, 1010, 753
 Arterio : Influence of unusual pupils in uncer-
 tained patients (H. K. Scott and G. A. Gernack),
 122 (10) — correspondence on, 875
Annals of Medical History, vol. 9, No. 5, 85; No. 6,
 247 — vol. 10, No. 2, 968
- Annotations.**
- Accidents, road, and ill-health, 1216
 Aircraft regulations, 1974, 957
 Air, review of, 491 in animal subjects, 1220
 Antivivipar, flying, 877
 Apple collection, under 6-8, 879
 Arachnoiditis, of toxicologic, 160
Archives of Disease in Childhood, 742
 Army, regular, medical officers for, 684
 Artificial lighting and work of weavers, 180
 Asthma research, progress in, 78
 Atmosphere, heating, 742
 Bee system for arthritis, 858
 Birthday honours, 1224
 Blackboards, yellow, 291
 Blindness, international survey of, 1164
 — prevention of, 789
 B.M.A. building and Royal Academy, 1167
 Brain, mineral content of, 457
 Bruckman, Laura, 345
 Calcium deficiency, 81
 Cancer, electrostatic detection of, 1272
 — of lung, 682
 — spontaneous recovery from, 555
Cancer in London, 1054
 Carcinoma, dental research into, 595
 Carcinoma, dental, 595
 Carcinoma, dental, 595
 Chemotherapy and cancer, 1216
 — in virus disease, 791
 Contact lenses, 1215
 Cooperation between physician, surgeon, and
 dentist, 25
 Cornwall, hospitals of, 621
 Certain arteries, action of, 151
 — occlusion, temporary, effects of, 139
 Culture, cosmetic, and medicine, 228
 Deaths, confidential certification of, 860
 "Dental benefit," 1274
 Dentistry, 1274
 D. P. Rankin, 1051
 D. P. Rankin, 1051
 Dissected sclerotic, treatment of, 1271
Dr. A. Cook's Book, 1220
 Drug, narcotic, traffic, in Egypt, 1319
 — in Egypt, 1319
- 629
- Androgen factors in breast tumours, 524
 Enzyme chemistry, 555
 Ephedrine, 729
 Epidemiological survey, weekly, 24
 Examinations, 1217
 Eye-strain, industrial, 458
 Factory, bumper, 458
 Freud in England, 1273
 Garden cities, idea of, 1111
 Gas-protective clothing, muscular work in, 1011

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION

EPITOME

OF

CURRENT MEDICAL LITERATURE

JANUARY TO JUNE, 1938

LONDON

Published at the Office of The British Medical Association, Tavistock Square, W.C.1, and
Printed by Eyre & Spottiswoode, Ltd., East Harding Street, E.C.4.

LIST OF ILLUSTRATIONS

SPECIAL PLATES

PAGE

Abortion, Analysis of 350 Cases of (R. G. Cooke) ..	facing 1062	Bronchiectasis, Pathogenesis of (P. P. Lee Lander and Maurice Davidson) ..	1014
Appendix, Unusual Tuberculous (D. J. Harries and Emrys Williams) ..	inset between 294 and 295	Buckmaster, George Alfred ..	44
Breasts, Bilateral Axillary (M. Christie) ..	facing 799	Butler, Harold Branson ..	48
Bronchiectasis, Pathogenesis of (P. P. Lee Lander and Maurice Davidson) ..	facing 1063	Carcinoma of Palate (John R. Nuttall) ..	840
Calcium and Phosphorus Deficiencies in Poor Human Diet (W. E. Gaunt, J. T. Irving, and W. Thomson) ..	facing 798	Chambers, James ..	1312
Cancer, Spontaneous Disappearance of (Digby Chamberlain) ..	inset between 526 and 527	Choleystectomy, Modified (Cecil F. Tucker) ..	338
Chloroma, Case of (H. Barsoum) ..	inset between 294 and 295	Clubbing, Familial, of Fingers and Toes (D. R. Seaton) ..	615
Chondrification of Patellar Ligament, Unusual Case of (J. M. Turner) ..	facing 29	Clubbing of Fingers and Toes associated with Congenital Lung Cyst (E. Montuschi) ..	1310
Cleptia, Hetero-lateral, of Right Kidney (R. Campbell Bogg) ..	inset between 1062 and 1063	Court, Sir Josiah ..	421
Empyema Cavities, Healing of (P. R. Allison) ..	inset between 294 and 295	Crawford, Sir Raymond ..	651
Epididymitis, Block Anaesthesia for Insertion of Radium to (Phyllis F. L. Daplyn) ..	inset between 526 and 527	Crichton-Browne, Sir James ..	231
Foot, Fragment of Needle in (J. P. Hastings) ..	inset between 1322 and 1323	Crutch Pad, Non-slip Rubber ..	1384
Fracture of Neck of Femur (H. A. Brittain) ..	inset between 798 and 799	Dental Emergencies in General Practice (G. G. Exner) ..	1376
Fracture of Neck of Femur. Another Method of Inserting Smith-Petersen Pin (H. B. Roderick) ..	inset between 28 and 29	Dionne Quintuplets ..	104
Gestation, Extra-uterine: Live Child (F. Stabler) ..	inset between 798 and 799	Dislocation of Eyeball as Complication of Oxycephaly (J. Sherne) ..	565
Gold Therapy, Complications of (T. H. Boon) ..	facing 799	Disseminated Sclerosis, Surgical Treatment of by Sympathectomy and Ganglionectomy (C. F. Koch and Eugene de Savitsch) ..	1254
Haemopneumothorax, Spontaneous (J. Maxwell) ..	inset between 798 and 799	Drip Feed for Divinyl Ether ..	1054
Hearing Aids in General Practice (F. J. Clemenson) ..	facing 1114 and 1115	Empyema Cavities, Healing of (P. R. Allison) ..	252
Hyperostosis Frontalis Interna (T. de Leheczky and A. Orbán) ..	inset between 1062 and 1063	Ethyl Chloride Anaesthetic Mask and Holder ..	733
Hyperparathyroidism, Case of (A. W. Fawcett) ..	facing 295	Extension Apparatus, Simple ..	677
Keratoplasty (T. H. S. Tizzard) ..	inset between 1322 and 1323	Foreign Bodies in Intestinal Tract ..	514
Lung Cyst, Congenital, Clubbing of Fingers and Toes associated with (E. Montuschi) ..	inset between 1322 and 1323	Fracture of Neck of Femur treated by Oblique Osteotomy (T. P. McMurray) ..	331
Lymphoid Tissue of Alimentary Canal (H. Gordon Thompson) ..	facing 28	Furnival, Percy ..	1076
Osteochondritis, Ischio-pubic (George D. F. McFadden) ..	inset between 1322 and 1323	Gastroscopy, Position of Patient in (Mermon Taylor) ..	891
Ovarian Dermoid, Rupture of (K. L. James) ..	facing 1322	Heberden Society's Medal ..	1375
Physiology and Pathology of Mental and Emotional States (F. A. Pickworth) ..	facing 294	Hill, Surgeon Vice-Admiral Sir Robert ..	900
Pneumonia, Lobar: Sulphuretic Abscess; Duodenal Fistula: Recovery (Sir A. J. Hall, G. S. Simpson, and J. L. A. Grout) ..	inset between 1062 and 1063	Keratoplasty (T. H. S. Tizzard) ..	1307
Pneumothorax (A. Morton Gill) ..	facing 527	King, Sir Frederic Truby ..	421
Pregnancy, Case of Abdominal (Ronald Reid) ..	inset between 1322 and 1323	Laurie Drip Bulb, Modified ..	1105
Pregnancy and Lactation Changes in Fibro-adenoma of Breast (Charles F. Geschlechter and Dean Lewis) ..	facing 526	Lipoma simulating Goltre ..	207
Prosthesis, New (A. Wynn Green) ..	facing 1323	Magnifier for Small Operations ..	339
Ribs, Abnormality of (W. A. Bellamy) ..	inset between 294 and 295	Mattress and Blankets for Fowler's Position ..	1264
Skull Bones, Persistent Overmoulding of causing Fits in an Infant (G. C. Gordon) ..	facing 29	Mental and Emotional States, Physiology and Pathology of (F. A. Pickworth) ..	264
Thymus, Malignant Tumour of (R. G. Prosser Evans) ..	facing 799	Nasal Sinusitis in Childhood (James Crooks) ..	915
Tuberculosis, Chronic Disseminated (F. A. H. Simmonds and W. Pagel) ..	facing 29	Needle, Suture ..	247
Tuberculosis in Infants (Dorothy Price) ..	inset between 294 and 295	Oedema, Instrument for Detection of ..	75
Tumour, Superior Pulmonary Sulcus (J. L. Ryce) ..	inset between 1322 and 1323	Ophthalmic Testing Unit, Portable ..	781
Tumours, Hereditary Bone, in Mice (F. C. Pybus and E. W. Miller) ..	facing 1322	Otitis Externa, Treatment of (F. C. W. Capps) ..	954
Wart, Plantar (R. M. B. MacKenzie) ..	inset between 526 and 527	Otitis Media, Treatment of (Mykes Formby) ..	1011, 1065

INDEX TO THE EPITOME FOR VOLUME I, 1938

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate but nearly synonymous headings—such, for instance, as Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Epithelioma, Malignant Disease, New Growth, Sarcoma, etc.; Child and Infant; Bronchocele, Goitre, and Thyroid; Diabetes, Glycosuria, and Sugar; Eye, Ophthalmia, and Vision, etc.

The Figures in this Index refer to the Number of the Paragraph, NOT the Page.

Bellagio...Lake Como
A delightful scene...bring-
ing to mind, maybe, many a happy
day during a well-earned rest.
And talking of travel, may we suggest
to practitioners when next this subject
looms on the horizon, that whether
they are themselves taking a holiday
for pleasure, or recommending their
patients to take one for health,
The World-wide Service of Cook's
is at their disposal...giving sound
advice on all phases of travel...
handling all those worrying details
that can so easily mar the enjoyment
of a holiday.
Advice without obligation from any
branch of

Two Valuable Numbers

JANUARY—FEBRUARY, 1938.

THE USE OF ENDOCRINES IN TREATMENT

The January number of *The Practitioner* contains a symposium on the use of endocrines in treatment. At the present time there is much uncertainty about this subject and the contributions in this number will help readers to estimate the value of these preparations. The contents include:—

THE USE OF THYROID PREPARATIONS

By G. R. MURRAY, M.A., M.D., F.R.C.P.
Emeritus Professor of Medicine, Victoria University,
Manchester.

THE USE OF PARATHYROID PREPARATIONS

By DONALD HUNTER, M.D., F.R.C.P.
Physician with charge of Out-patients, London Hospital.

THE USE OF ADRENAL HORMONES

By S. LEVY SIMPSON, M.A., M.D., M.R.C.P.
Physician, Wilkesden General Hospital.

THE USE OF PITUITARY PREPARATIONS

By P. M. F. BISHOP, B.M., B.Ch.
Clinical Endocrinologist, Guy's Hospital.

THE USE OF FEMALE SEX HORMONES

By DOUGLAS MACLEOD, M.S., F.R.C.S., M.C.O.G.
Surgeon to Out-patients, St. Mary's Hospital, Queen
Charlotte's Maternity Hospital, and the Hospital for Women,
Soho Square.

THE USE OF MALE SEX HORMONES

By E. W. RICHES, M.C., M.S., F.R.C.S.
Assistant Surgeon and Assistant Urologist, Middlesex Hospital.

This number also contains articles of general medical interest and
DIET IN HEALTH AND DISEASE

VII. Diet in Obesity and Endocrine Disorders.

DISORDERS OF DIGESTION

The February number of *The Practitioner* will contain a symposium on abdominal pain and disorders of digestion. The articles which are essentially practical include the following:—

THE DIAGNOSIS AND TREATMENT OF ABDOMINAL PAIN

By JOHN MORLEY, CH.M., F.R.C.S.
Professor of Surgery, Manchester University; Surgeon, Man-
chester Royal Infirmary.

ABDOMINAL PAIN OF THORACIC DISEASE

By MAURICE DAVIDSON, M.D., F.R.C.P.
Physician, Brompton Hospital for Diseases of the Chest

THE SIGNIFICANCE AND TREATMENT OF INDIGESTION

By ERNEST BULMER, M.D., F.R.C.P.
Physician, General Hospital, Birmingham.

THE SIGNIFICANCE AND TREATMENT OF VOMITING IN ADULTS

By GEOFFREY EVANS, M.D., F.R.C.P.
Physician, St. Bartholomew's Hospital.

THE SIGNIFICANCE AND TREATMENT OF DIARRHOEA IN ADULTS

By S. W. PATTERSON, M.D., F.R.C.P.
Physician, Ruthin Castle.

THE SIGNIFICANCE AND TREATMENT OF OBSTINATE HICCUGH

By E. BELLINGHAM SMITH, M.D., F.R.C.P.
Physician, St. George's Hospital.

LABORATORY METHODS IN THE DIAGNOSIS OF GASTRO-INTESTINAL DISORDERS

By R. G. L. WALLER, M.B., B.S., F.R.C.P.
Director of Pathological Department, West London Hospital.

This number also contains articles of general medical interest,
including

THE MANAGEMENT OF INSOMNIA

By HENRY COHEN, M.D., F.R.C.P.
Professor of Medicine, University of Liverpool.

DIET IN HEALTH AND DISEASE

VII. Diet in Kidney Disease.

By ROBERT PLATT, M.D., F.R.C.P.
Physician, The Royal Infirmary, Sheffield.

KIMPTON PUBLICATIONS**VOLUME II****TEXT-BOOK OF OPHTHALMOLOGY****JUST READY**

By SIR W. STEWART DUKE-ELDER, M.A., D.Sc. (St. And.), Ph.D. (Lond.), M.D., Ch.B., F.R.C.S.
Surgeon Oculist to H.M. The King; Ophthalmic Surgeon, St. George's Hospital; Honorary Research Associate, University College, London; Lecturer in Ophthalmology, St. George's Hospital Medical School, etc.

Volume II—Clinical Methods of Examination, Congenital and Developmental Anomalies, General Pathological and Therapeutic Considerations, Diseases of the Outer Eye.

Crown Quarto. 996 pages, with 742 Illustrations, including 24 Coloured Plates.

Cloth.

Price £3 3s. net.

This volume is devoted in the first place to a consideration of the clinical methods employed in the objective and subjective examination of the eyeball. Congenital and Developmental anomalies of the eye are then discussed followed by a section on diseases of the eye including general pathological and therapeutic considerations. The remainder deals with diseases of the outer eye.

NEW (FIFTH) EDITION**JUST READY****A PRACTICAL TREATISE ON DISEASES OF THE SKIN**

By OLIVER S. ORMSBY, M.D.

FIFTH EDITION, REVISED AND ENLARGED.

Royal Octavo, 1,334 pages, with 658 Engravings and 3 Coloured Plates.

Cloth.

Price 52s. 6d. net.

"No serious student need hesitate to purchase the book, but it is to the experienced practitioner that it will make most appeal."
—The Lancet.

NEW BOOK**ATLAS OF SKELETAL MATURATION****JUST READY**

By T. WINGATE TODD, M.B., Ch.B.Manc., F.R.C.S.Eng.

Demy Quarto, 75 Radiographic Plates of the Hand.

Cloth.

Price 31s. 6d. net.

This atlas contains 75 half-tones of roentgenograms selected as typical of the successive stages in ossification in the hand of boys and girls from 3 months until the date in adolescence when all epiphyses are united. There are more than a hundred pages of text dealing with general problems involved in the study, and specific problems of the hand.

NEW BOOK**THE ESSENTIALS OF PHARMACOLOGY,****JUST READY****MATERIA MEDICA AND THERAPEUTICS FOR MEDICAL STUDENTS**

By D. M. MACDONALD, M.D., F.R.C.P.E.

Fcap Octavo, 279 pages

Cloth.

Price 7s. 6d. net. (Postage 4d.)

The essential idea which suggested an addition to an already large number of text-books is to impress on the student the wisdom of a wider and more practical knowledge of pharmacy and materia medica, in order to cultivate intelligent prescribing on the one hand, and to avoid slavery to proprietary preparations and stereotyped formulae on the other.

NEW (SIXTH) EDITION**METHODS OF TREATMENT****JUST READY**

By LOGAN CLENDENING, M.D.

SIXTH EDITION, REVISED.

Royal Octavo, 879 pages, with 193 Illustrations.

Cloth.

Price 42s. net.

This book furnishes an outline of all the methods of treatment in internal medicine and gathers together all therapeutic procedure, which material is usually widely separated in medical literature.

"The most attractive book of its kind we know... a mine of wisdom."—*Irish Journal of Medical Science.*

NEW (SECOND) EDITION**THE MANAGEMENT OF****JUST READY****FRACTURES, DISLOCATIONS AND SPRAINS**

By JOHN ALBERT KEY, B.S., M.D. and H. EARLE CONWELL, M.D., F.A.C.S.

SECOND EDITION, REVISED AND ENLARGED.

Large Octavo, 1,246 pages, with 1,222 Illustrations.

Cloth.

Price 52s. 6d. net.

A complete account of modern ideas and methods which can be depended upon to lead correctly in the proper care and management of all types of fractures, dislocations and sprains.

"A very comprehensive work to which practitioners will not refer in vain."—*British Medical Journal.*

NEW (SECOND) EDITION**CRIPPLED CHILDREN****JUST READY**

Their Treatment and Orthopaedic Nursing.

By EARL D. McBRIDE, B.S., M.D., F.A.C.S.

SECOND EDITION, REVISED AND ENLARGED.

Royal Octavo, 379 pages, 195 Illustrations.

Cloth.

Price 18s. net. (Postage 8d.)

The intention of this book is to supply information which will be of interest to those who have the care of crippled children, assisting them in the recognition and treatment of the more common orthopaedic conditions, particularly in the early stages when so much can be accomplished. Each section contains a clear statement of the nurse's duties.

NEW (SIXTH) EDITION**A DIABETIC MANUAL FOR****JUST READY****THE MUTUAL USE OF DOCTOR AND PATIENT**

By ELLIOTT P. JOSLIN, M.D.

SIXTH EDITION, THOROUGHLY REVISED.

Small Octavo, 219 pages, 48 Engravings and a Coloured Plate.

Cloth.

Price 10s. 6d. net. (Postage 6d.)

Proinsulin insulin has given the diabetic an opportunity to live like a normal individual. The sixth edition of this famous manual shows the patient how to do it, and supplies him with everything that he needs to know.

263, High Holborn**HENRY KIMPTON****London, W.C.1**

In acting as an executor or trustee, the Westminster Bank aims at putting itself in the position of a private trustee. It is therefore its practice to employ the family solicitor, if there is one, or any other solicitor the client may name; by such means the Bank succeeds in combining domestic tradition with business efficiency. A book showing the advantages of corporate executorship and the terms of appointment may be had at any branch or at the branch situated in B. M. A. House, Tavistock Square, W.C.1

THE PHYSIOLOGICAL VALUE OF THE BANANA

III. Ash or mineral matter: The amount of ash (0.8 per cent average) is high for a fruit. It is alkaline, a point to be remembered in connection with intestinal weakness.

Small quantities of iron, copper and iodine are also present.

The iron content averages 6.4 parts per million, a satisfactory amount for a fruit. The presence of a minute amount of copper assists the due assimilation of the iron into the blood.

The trace of iodine, being more readily assimilable when normally present in a food than when added in the form of a salt, has its full beneficial action upon the thyroid gland.

N.B. Therapeutically, the banana is most valuable when fully ripe. In the fully ripe banana the soluble sugars evolved are approximately 9 per cent. cane sugar and 4 to 5 per cent. each of glucose and fructose. A banana is ripe when all green has disappeared from the skin and brown spots have formed on the yellow surface.

GAS-AIR ANALGESIA

The demand for a simple portable apparatus for the administration of N_2O and air mixture, has led to the production, by this company, of the "Queen Charlotte's" Gas-Air Analgesia Apparatus. Features of this apparatus are perfect safety, low cost, portability, compactness and simplicity. Models of this apparatus have been in successful use, day and night, at Queen Charlotte's Hospital during the past year. Practitioners are invited to apply for an illustrated booklet, describing the apparatus, and giving full particulars of prices.

ANTISEPSIS

The full development of Antiseptis demands an agent which, while efficient, does not damage human tissues, nor inhibit the normal function of the natural defences against infection. That Verpine is efficient has been proved during years of clinical trial. When used at fully antiseptic strengths Verpine has negligible effect on human tissues, while one of its active principles encourages natural resistance to infection by promoting leucocytosis, and is a protoplasmic stimulant. Verpine, moreover, is agreeable to use, and possesses a pleasant, refreshing odour.

RADIOSTOLEUM EMULSION WITH VITAMIN C

Physicians, particularly pediatricians, will recognise the value of the new B.D.H. vitamin preparation Radiostoleum Emulsion with Vitamin C. This is a palatable and easily-digested emulsion and contains in one fluid drachm (1 teaspoonful) 6000 international units of Vitamin A, 1200 international units of Vitamin D and 200 international units of Vitamin C. The administration to infants, whether breast-fed or bottle-fed, of Vitamins A

and D in the form of an oil and Vitamin C in the form of orange juice sometimes presents difficulty. This is obviated by the use of Radiostoleum Emulsion with Vitamin C which can be given direct from a spoon or mixed with the feed.

Samples for clinical trial are available on request.

Radiostoleum Emulsion with Vitamin C is issued in bottles containing 4 fl. oz. at 2/6 per bottle.

THE BRITISH DRUG HOUSES LTD. LONDON N.1

the scientific contraceptive

MIL-SAN is a bland, non-injurious, spermicidal jelly independent of variable physiological conditions of moisture or temperature. Since there is nothing to melt, dissolve or foam, MIL-SAN is immediately effective.

The formula of MIL-SAN is based on biological principles in harmony with the natural chemical and bactericidal balance of the vagina. Its spermicidal efficiency is due to: (a) A low pH secured by the reinforcing action of several acids which ensures the immediate immobilization and death of spermatozoa, despite the buffering action of the seminal fluid; (b) A low surface tension which causes the jelly to spread rapidly and to penetrate the rugae of the vaginal and cervical mucous membrane; (c) A degree of viscosity which ensures that it shall adhere to the cervix and upper vaginal tract and fornices, forming a chemical barrier preventing the penetration of spermatozoa into the os uteri.

The method of applying the jelly is simple, hygienic, and proof against carelessness. Each application of 7 c.c. is contained in a specially

made strong glass tube sealed at one end with a cork, at the other by a hard wax plug. In use the cork is removed, a bulb fitted behind the wax plug and the tube inserted. Compression of the bulb forces the wax plug down the tube and ejects the contents. The empty tube, which is thrown away, proves the application and ensures the quantity. There is nothing to fill, nothing to clean. Each application is hygienic and complete.

MIL-SAN does not deteriorate and is not affected by climatic conditions.

There are no contra-indications to the use of MIL-SAN with a dependable condom or a properly fitted occlusive pessary. It is only by such combined use that the consequences of misuse of one or other of the methods can be minimized and the maximum practicable security obtained.

Literature setting out the ingredients and full particulars, together with a box of specimen tubes for examination, are sent on request to members of the medical profession.

Oral Vaccine for the prevention of Colds and Influenza

Since Genora brand Oral Vaccine was introduced to the Medical Profession last Winter, extensive clinical and laboratory tests have shown that it establishes a high degree of immunity against colds and influenza; the oral vaccine has also proved successful in the treatment of chronic bronchitis and similar respiratory infections.

This vaccine contains hæmolytic streptococci, in addition to other organisms incriminated in the causation of coryza and influenzal infections. It has been found that the ingestion of the oral vaccine against colds and influenza also develops immunity to diseases caused by hæmolytic streptococci.

Particulars concerning Genora brand Oral Vaccine will be found in the new brochure on Vaccine Therapy which has recently been published by Genatosan Ltd. This booklet also gives information regarding a wide range of vaccines administered by hypodermic injection and the standard types of Local Immunity Products. A copy of the brochure will gladly be supplied to any physician on request.

OVALTINE

IN NUTRITIONAL CRISES

WHILE the average adult is able to maintain a healthy existence on the ordinary everyday diet, there are certain periods in the life of each individual when an increased demand for the vital food elements arises. Outstanding examples are the period of adolescence, the pregnant and nursing states and the stage of convalescence after severe and lowering illnesses.

"Ovaltine" is an eminently satisfactory adjunct to the ordinary dietary at all such times. Composed of fresh, full-cream milk, eggs and malt extract in proportions adjusted to meet physiological requirements, it provides, in an agreeable form, calcium, phosphorus, vitamins and other important food elements.

"Ovaltine" is a metabolic stimulant and digestive which assists the assimilation of other foods and promotes general good health. It can, therefore, be taken regularly with advantage in place of tea, coffee, or other beverages. A noteworthy feature is its delightful taste which is appreciated by people of all ages.

A liberal supply for clinical trial sent free on request.

'PANOPEPTON'

A Food for the Sick

Which measures up in the present day science and concept in nutrition—established as a resource of especial value by the extensive experience of clinical test.

'PANOPEPTON' is the entire substance of beef muscle as brought into hydrolysed solution in contact with gastric mucosa juice. This in combination with the substance of wheat berry as converted into solution by pancreas gland tissue juice.

'PANOPEPTON' presents for the nutrition of the sick these basic food materials in the form in which they are set free and elaborated in the normal digestive scheme.

'PANOPEPTON' is a food—agreeable—grateful, even to the very sick, requires no preparation.

Supplied in 12-oz. bottles.

	CALORIES PER OZ.	170

A typical example of the high nutritive values retained in Heinz Strained Foods. (Figures show percentages on the wet basis)

Vegetable and fruit purées, rich in mineral salts, vitamins and other soluble nutriment, constitute the perfect diet for infants and cases of nutritional anaemia.

But despite the wide approval shown by physicians, and a growing appreciation of this dietary by mothers, progress has hitherto been slow, owing to the practical difficulties encountered in home preparation.

The use of vegetables not truly fresh, mechanical losses through oxidation when boiling, and inefficient sieving out of the harsh fibres, inevitably impair the quality of the home-produced preparation.

Now, with the marketing of a range of strained foods by H. J. Heinz Co. Ltd., vegetable and fruit purées containing all necessary dietetic values are available in convenient bulk and form.

Heinz Strained Foods are prepared with all the advantages of the best factory method. The vegetables are specially grown in those areas where soil and climate combine to produce the best; they are harvested when they are just right, and cooked within a few hours of being garnered.

First, the ingredients are scrupulously cleaned. Cooking by light steam pressure in vacuum containers follows, leaving the contents perfectly disposed for comminution by extrusion, and at the same time ensuring retention of the essential juices and mineral constituents. Fine sieving having removed all fibres of a harsh or irritant nature, the purée is then adjusted to an acceptable consistency and sealed in vacuo, the sealed containers being immediately subjected to sterilization under constant conditions of time and temperature.

The purées thus offered are uniform, convenient and of the highest possible nutritive content.

NOTE: Glass containers are not used owing to the deleterious effect of light on the value and palatability of the purées

Early diagnosis and treatment in Diphtheria

FOR DIAGNOSIS

BRAHDY "RAPID CULTURE" TUBES *Lederle* permit identification of *Ci. diphtheriae*; if present, *four hours* after the culture is taken, as compared with the 18 to 36 hours required for Loeffler cultures. The four-hour incubation period does not permit an overgrowth of contamination organisms, which do not grow well on this medium.

The technique is simple and convenient and the organisms grow with characteristic morphology.

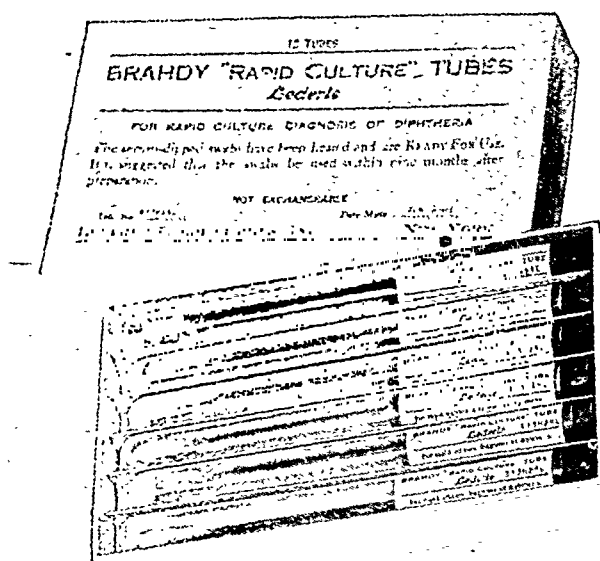

FOR TREATMENT

DIPHTHERIA ANTITOXIN "GLOBULIN MODIFIED" *Lederle*, the recently announced antitoxin which is characterised by—

- its low protein content.
- its high concentration.
- its low viscosity.
- its lowered property of inducing serum disease.

The earlier in the disease antitoxin is given, the more certain and rapid is its effect. The first injection should be large enough to control the disease. One large dose given early is more efficient than the same amount given in divided doses.

The increased potency and reduced protein content of the *Lederle* product has resulted in a greater ease of administration of adequate dosage and, of the greatest importance, a measurable lowered property of inducing serum sickness.

B.D.H. VACCINES AND SERA

An Announcement

The British Drug Houses Ltd. have pleasure in announcing that their new laboratories for the preparation of vaccines and sera are now complete.

As a result of their very recent construction, these laboratories are equipped to meet all the demands and modern advances of immunological science; in consequence, in the preparation of the B.D.H. Vaccines and Sera the most recent methods are employed, and the products supplied comply in every instance with the requirements of the Therapeutic Substances Regulations. Physicians are able, therefore, to prescribe these new B.D.H. products with the same confidence that they place in the established B.D.H. preparations.

An illustrated brochure indicating both the completeness of the laboratory equipment and the range of vaccines and sera available has been distributed; any member of the medical profession who has not received a copy is invited to apply for one.

THE BRITISH DRUG HOUSES LTD. LONDON N.1

COCAINE—With 1% cocaine solution, an average of 173 seconds elapse before the touch of a wooden applicator on the eye-ball is no longer felt.

BUTYN—With a 1% solution of Butyn, (Abbott), an average of only 63 seconds elapse before the touch of a wooden applicator is no longer felt.

COCAINE—With 1% cocaine solution the duration of anaesthesia is no longer than that obtained with 1% Butyn solution. Note the dilatation.

BUTYN—With 1% Butyn solution, anaesthesia persists for approximately as long as when 1% cocaine is used. Note absence of dilatation.

ANESTHESIA

RAPID • PROFOUND

Among local anaesthetics—including cocaine—which are effective on intact mucous surfaces, Butyn is unique in its ability to produce rapid, profound and prolonged anaesthesia. Butyn is widely used and is recommended for topical application in operative procedures on the eye, nose and throat, as well as for use in genito-urinary work. ● Butyn 2% Solution, the most widely used preparation of the drug, has proved to be as effective clinically as a 5% solution of cocaine. Used in the eye, Butyn does not affect the accommodation nor ocular tension. Neither does it cause drying of the conjunctiva as does cocaine. Two or three drops of the 2% Solution in the eye are sufficient for the removal of impacted foreign bodies or for the relief of pain due to abrasion of the cornea.

For operations, stronger solutions (up to 5%) are employed. ● Topical applications of Butyn 2% Solution are sufficient for operations in the nose and for surface anaesthesia in the throat. For genito-urinary use, Butyn gives excellent results even in cases where the mucosa is extremely painful. ● Butyn is non-narcotic and is not habit-forming. Its solutions are slightly antiseptic, stable and may be boiled. ● Butyn 2% Solution is available in 1-ounce bottles through prescription pharmacies. Butyn is also issued in 3-grain tablets and in powder form. Descriptive literature will be sent on request. The coupon is for your convenience.

CHILBLAINS

(in the thin hypotonic scrofulous type of patient) constitute an indication for the administration of "Halibol"-Calcium Capsules.

Each capsule of this preparation has the following contents:

Vitamin A—8,000 international units	} The amounts in about 3 fluid drachms of good standard cod-liver oil.
Vitamin D—2,000	
(1 milligram of Calciferol)	
Calcium Sodium Lactate—5 grains	

The vitamins are provided in the form of 0.2 c.cm. (about 3 minims) of "Halifool" (specially prepared halibut-liver oil with irradiated ergosterol). "Halibol"-Calcium Capsules, moreover, meet the demand for a convenient prophylactic preparation to be administered during pregnancy. Deficiency of vitamin D, which is liable to occur in pregnancy, leads to osteomalacia and probably to dental caries. Vitamin A is necessary for correct growth. The use of "Halibol"-Calcium is indicated also in menorrhagia, purpura, rickets, marasmus, tuberculosis, and other debilitating diseases.

Descriptive Literature will be sent on request.

THE HISTORY OF THE PREVENTION OF PUERPERAL FEVER*

BY

MILES H. PHILLIPS, M.D. (Hon.), B.S., F.R.C.S., F.C.O.G.

Emeritus Professor of Obstetrics and Gynaecology, University of Sheffield

This title having proved too ambitious a one for a lecture of an hour's duration, I have found it necessary to restrict my subject to a theme which can be indicated by the following words from Geoffrey Chaucer's *Canterbury Tales*—the words, written in 1389, with which the Manciple admonishes the drunken cook:

"Hoold cloos thy mouth man
Thy cursed breeth infecte wole [will] us alle."

Consideration of the study of the development of a therapeutic or a prophylactic measure will often be found to strengthen our intention to employ the measure in question.

The Principle of Contagion

The history of the prophylactic measure which I shall later on advocate may be held to begin about the middle of the nineteenth century. At that time a fundamental principle, that of contagion, was at last accepted by most of the leading obstetricians of the day. This theory had been long since suggested by Alexander Hamilton, in 1781, demonstrated by Alexander Gordon, in 1795, and more recently supported by Oliver Wendell Holmes, in 1843. It suits my purpose to cite only one of these converted authorities, one who had already conferred a great boon on parturient women by the introduction of chloroform.

In the discussion which followed a paper on puerperal fever read by Dr. Arneth of Vienna before the Medico-Chirurgical Society of Edinburgh on April 16, 1851, Dr. James Y. Simpson said: "But in this country we do not believe that the disease is usually propagated directly from individual to individual, but indirectly, through the medium of a third person; and that person generally the medical attendant or nurse." In the same speech Simpson confesses that in 1836, when he had his first experience of puerperal sepsis in his own practice, he had "no full and proper belief in the contagious propagation of puerperal fever." Otherwise, he leads us to infer, he would not have gone from active participation in necropsies in two cases of fatal puerperal sepsis to four cases of midwifery, all of which became infected.

It should especially interest a Manchester audience, and particularly those who are members of the staff of St. Mary's Maternity Hospital, to hear or recall that Simpson had been not a little influenced by reading an account of an outbreak of puerperal sepsis in the district maternity practice of the Manchester Lying-In Charity—the forerunner of the present-day St. Mary's Maternity Hospital. Simpson had read of this in a letter published in the *London Medical Gazette* in 1832—under the heading "Is Puerperal Fever Infectious?"—by Dr. John Roberton.

* The Lloyd Roberts Memorial Lecture, delivered at St. Mary's Maternity Hospital, Manchester, on November 10, 1937.

Dr. Roberton was appointed to the hospital staff in 1827, and he was the last member to bear the title of man-midwife, this being changed to surgeon in 1828. His letter had been written in response to a communication to the *Gazette* by Dr. William Campbell, and it is advisable to quote directly from it, as Simpson, apparently trusting to memory, is inaccurate in not a few of the figures he gives. Dr. Roberton begins thus:

"Sir,

"The letter of Dr. Campbell on puerperal fever, which appeared in the *Medical Gazette* of December 10, has recalled my attention to certain facts in my possession, calculated to throw some light on the query which heads this communication.

"On the question of infection" (Dr. Campbell observes) "I am as much as ever impressed with the belief that unless the practitioner has been engaged in the dissection of the bodies of those who have fallen victims, the disease cannot be conveyed by him from females labouring under it to others recently delivered; but if he have been so engaged, I have strong reasons for believing that he may be the means of propagating it." My experience," Roberton comments, "is not in unison with this conclusion. On the 4th of January last [1831] a meeting of the medical officers of the Manchester Lying-in Charity was summoned in consequence of a great mortality having occurred, during the four preceding weeks, among the patients of one of the midwives. The circumstances we found to be these: Mrs. A. B., a midwife in great practice among the patients of the Charity, had on the 4th of the preceding month delivered a poor woman, who soon died with symptoms of puerperal fever. From this date to the 4th of January inclusive—exactly one month—this midwife delivered thirty women residing in different parts of an extensive suburb, of which number sixteen caught the disease, and all of them ultimately died. These were the only cases of puerperal fever which had for a considerable time occurred in Manchester. The midwives, commonly twenty-five in number, deliver, on an average, ninety women per week. Now of this number delivered during the month in question, none had puerperal fever except the patients of Mrs. A. B. Yet all this time this woman was crossing the other midwives in every direction, scores of the patients of the Charity being delivered by them in the very same quarters where her cases of fever were happening. . . .

"The decision of the medical officers of the Charity was to the effect that Mrs. A. B. should abandon her practice for a short period, and go into the country."

Dr. Roberton concludes:

"The fact that sixteen cases of puerperal fever occurred in one month in the practice of a single midwife, while the patients of the other midwives were exempted from the disease, leads naturally to the conclusion that this midwife was the medium of communicating (I take not upon myself to say in what manner) the malady from one woman to another—from one affected with the fever to another in health."

PRODUCTS OF THE GLAXO LABORATORIES

OSTOMALT The 4-Vitamin Malt Extract

For young and growing children and for debilitated convalescents, Ostomalt builds a barrier against winter ills. Besides its natural vitamin B, special additions of vitamins A, C and D ensure the orderly growth of tissues and provide the best defence against disease and relapse. Agreeably flavoured and entirely free from fishy oils. Teaspoon dosage suffices. In jars, 1/9 and 3/- . Dispensary jars (7 times 3/- size), 17/-

PRODUCT OF THE
GLAXO LABORATORIES

FAREX The PROTECTIVE Cereal Food

This nutritious composite food has been specially devised to provide—in a blended cereal base—a reliable, measured supply of iron, calcium, phosphorus, other minerals and vitamins A, B and D. Doctors find Farex a valuable daily addition to the diet (e.g. as a "tonic breakfast")

PRODUCT OF THE
GLAXO LABORATORIES

in cases of debility, muscular atonia, neurasthenia, dyspepsia. Ready to serve. Can be flavoured to taste. In pourer cartons, 1/- and 1/9

ADEXOLIN Concentrates of Vitamins A & D

All prices (not applicable in I.F.S.) are subject to usual professional discount.

To protect the susceptible at this time of year, to shorten the course of early colds, or to check recurrent infection, immediate administration of Adexolin vitamins A and D is urged. The concentration of vitamins in Adexolin permits utmost flexibility of dosage. 6,000 international units of vitamin A and 1,000 of D in each 3 m. capsule; 12,000 of A and 2,000 of D in each cc. of tasteless liquid. CAPSULES: Boxes of 25, 2/6; 100, 7/6; 500, 30/6. LIQUID: 1/2 oz. phials, 2/6; 2 oz. bottles, 7/6; 4 oz., 12/6; 8 oz., 22/6

PRODUCT OF THE
GLAXO LABORATORIES

OSTOCALCIUM TABLETS

(Calcium sodium lactate with vitamin D)

When calcium is needed, vitamin D is needed also. Ostocalcium Tablets incorporate both. Each tablet contains 7 1/2 grs. calcium sodium lactate—rapidly assimilable form of calcium—together with 500 international units of vitamin D. Ostocalcium tablets therefore supply an ideal preparation for routine administration in disorders of calcium-phosphorus metabolism. In tins of 50, 2/3; 100, 4/-; 500, 12/6; 1,000, 17/6

GLAXO LABORATORIES LTD. GREENFORD, MIDDLESEX. BY POST 3434

addition to streptococci it includes staphylococci, the colon bacillus, pneumococci, the gonococcus, the bacillus of diphtheria, of tetanus, of typhoid even, the *Bacillus aerogenes capsulatus* of Welch, and the *Bacillus pyocyaneus*.

The Introduction of Antiseptics

The discovery of bacteria was quickly followed by Lister's introduction, in 1867, of the chemical antiseptic with which microbes in septic wounds or on the skin of the patient or the hands of the surgeon could be rendered inert. Lister, employing the method with meticulous care, was soon able to revolutionize surgical operative practice. Certain obstetricians—and one must mention Hayes of the General Lying-in Hospital, London, and Tarnier of Paris—convinced of the identity of surgical and puerperal sepsis, introduced antiseptics into their midwifery practice, with a striking reduction in the occurrence of infection in the maternity hospitals they controlled. However, we must not forget that many years previously Robert Collins of the Rotunda (in 1829) and Semmelweis in Vienna (in 1847) had used a solution of chloride of lime to destroy the unknown virus of infection.

The use of antiseptics soon became the first line of defence in the campaign against puerperal sepsis, and so it remains to this day. Many forms have been introduced since the days of Lister's carbolic acid. The search for the ideal antiseptic has a story of its own, which some consider is not yet complete; many others are perfectly satisfied with the one of their choice.

Although the incidence of puerperal sepsis has been greatly diminished, the dread disease has by no means been eliminated. Sporadic cases are of not infrequent occurrence, and even epidemics occur in hospital as well as in private practice. Puerperal sepsis is still one of the chief causes of puerperal mortality. Some authorities maintain that this is only the consequence of the neglect or the inefficient use of the antiseptic ritual. Others, doubting this simple solution of a grave problem, have with infinite pains searched more and more deeply into the life-history of the microbes chiefly concerned, and particularly into their habitat—the lair in which they must be destroyed or between which and the woman in labour an effective barrier must be set up. Since Pasteur's day it has been recognized that streptococci cause the great majority of the serious and fatal infections. They have been intensively studied by devoted specialists, and gradually the complexity of the nefarious clan has been revealed. Streptococci are subdivided according to the way in which they grow: some are haemolytic, others have no action on blood, while others will only grow in the absence of oxygen. Of the haemolytic strains only one group (Group A) is capable of causing severe infection in human beings, and this group is further subdivided by intricate serological means into about twenty-five distinct types. Some half of these known types have been found to play a causative part in puerperal infections.

The history of these investigations is beyond my purpose and, indeed, my powers. I have chosen to attempt to unravel the story of the tracking of the villain to his chosen lair and the provision of a means to intercept him at its exit. I refer, of course, to the human throat and the surgical face mask.

The source of the problematical virus had for long been a matter of speculation, the most favoured being decomposing animal matter associated with necropsies and dissections, cancers, and surgical wounds, especially where

midwifery cases and cases of general disease were housed under the same roof. Semmelweis and Holmes both laid down rules of conduct against these dangers. The means of conveyance were debated: clothes, the hands, the atmosphere were accused.

Charles Meigs, the anti-contagionist already quoted, ridiculed the idea: he tells of

"another friend of mine who had been chased, so to speak, by a series of such cases, seventy in all, left the city, was absent many days, and on returning, shaved his head, got a new wig, new clothes, new gloves, new pencil. He went into a bath, was washed clean, dressed himself, and then visited and assisted a woman in labour who was seized next day and died." If the man "was poisonous," says Meigs, "how was he so? Everything except the man was new. He could not have carried the atmosphere of his last patient's chamber with him to the country, keep it about him like an invisible cloud," and "then carry it into the last patient's chamber to destroy her with exhalations more pestiferous than the breath of Cacus."

By the irony of fate Meigs's satirical flights of imagination had brought him near the truth: the "new pencil" wetted by the lips might have infected the doctor's fingers: the "exhalations more pestiferous than the breath of Cacus" may well have conveyed virulent streptococci. In fact this was so; for Meigs's friend was no other than the unfortunate Dr. Rutter of Philadelphia, who within five years had ninety-five cases of puerperal infection in his practice, with eighteen deaths. It is known that he suffered from ozaena due to chronic rhinitis.

Many years later, in 1924, two outbreaks of pyrexia at the Portsmouth Municipal Maternity Hospital were proved to be associated with the presence of a pupil midwife who suffered from atrophic rhinitis and in whose nose haemolytic streptococci were found.¹

Relation of Streptococcal Sore Throats to Puerperal Fever

The discovery of microbes gradually led to the eclipse of mere conjectures; theories could henceforth be scientifically tested. The comment of Dr. John Clarke (1793)—that "it is a curious circumstance that before the attack of the epidemic of lying-in women at Paris in the year 1746, in the month of January, there had been an epidemic low fever, with an ulcerous sore throat"—has thus been illuminated by the discovery that certain members of Group A of the haemolytic streptococci can be much more readily found in human throats at the time of year when puerperal sepsis is most prevalent. Alexander Gordon, who wrote in 1795 on the "Epidemic Puerperal Fever of Aberdeen (1789-92)," prepared a set of tables showing the simultaneous prevalence of "inflammatory sore throat." Fleetwood Churchill (1849) speaks of the "epidemic season," between November and May, and shows that the eighteenth century writers on puerperal sepsis—Leake, Armstrong, Campbell, Hey, Joseph and John Clarke—all agreed that the "puerperal fever prevails most during the winter and spring months."

Although streptococcal sore throats are most prevalent from October to May, demanding specially careful precautionary measures in surgical and midwifery practice, they may occur at any season, and so the same precautions are actually always desirable. In my quest for the discoverer of this source of contagion I arrived at a paper by W. Hübener (1898) based on experimental work carried out at the Breslau Surgical Clinic of Professor Mikulicz. Hübener begins by referring to the pioneer work of

¹ *British Medical Journal*, 1924, 2, 623.

The modern conception of a carrier had not of course been considered in those days. Within the last few years I myself have taken a small part in the investigation of two similar epidemics in the practices of one only of each of two groups of midwives—both of whom had clean records for several years. In each epidemic it was clear that some of the patients were infected during the puerperium and not at the labour. In each instance haemolytic streptococci were found in the throats of the midwife, and both were cured by removal of the diseased tonsils.

Simpson came to the conclusion that the unfortunate midwife in question must have been, unlike the other midwives, "connected with some form of that morbid principle or virus to which pathologists give the name contagion." No one at that time had any conception of the nature of that virus. Some even held it could never be known. Charles Meigs of Philadelphia, a bitter opponent of Oliver Wendell Holmes's views, wrote in his *Treatise on Obstetrics*, 1856:

"The student will naturally be desirous to learn, if childbed fever be really a contagious disease, what the principle of that contagion is; and I apprehend that here he shall have to rest content with the sound of the word contagion, a word which, being interpreted, means communicable from person to person, or by individual to individual. This is the whole meaning of the word; for, as to how, and the what, no man hath yet obtained the least definite notion, since no man hath known or can know what a miasm or a contagion is. Miasm and contagion are words, nothing more: they represent no precise material idea of the mind."

Dr. Robertson's account of the Manchester epidemic had been previously cited by Oliver Wendell Holmes (1843).

The High-pressure Sterilizer

It is also of great interest to record that John Robertson played a small part in an investigation which led to the invention of the high-pressure sterilizer, so essential to modern aseptic technique. Dr. William Henry, the famous physicist (1775-1836), also of Manchester, was making experiments on sterilization by heat, at the request of a cotton importer, in the hope of preventing the introduction of plague in cargoes of Egyptian cotton landed at Manchester. Dr. Henry (1831) states that "the most important point to be ascertained, and that on which the utility of the inquiry hinges, is whether temperature below 212° Fahrenheit is capable of destroying the contagion of fomes." To test the effect of different temperatures, for varying periods of time, Henry made use of fresh vaccine lymph. Among others, Dr. John Robertson, "one of the surgeons of the Manchester Lying-In Hospital," supplied Dr. Henry with the vaccine lymph. The double-jacket steam sterilizer was devised as the direct result of these experiments.

Thus this powerful means of destroying the cause of contagion was invented and in use thirty years and more before it was proved that the actual fomes were the micro-organisms of Anthony van Leeuwenhoek, microscopic protozoa which he had discovered—in water in 1675, and, in 1681, in material from the human mouth. It was ignorance as to the nature of these fomes—of the "precise material" of Charles Meigs, of the body or substance which could be conveyed by a third person from one patient to another—that had long delayed the wide acceptance of the theory of contagion. The final acceptance had been actually based on circumstantial evidence alone.

Years were to elapse before the elusive and, as it proved to be, microscopic malefic object was discovered,

although, one is amazed to find, the transcendent brain of William Harvey had in 1651 used the term "fomes" and had conceived the idea of "seeds of epidemic and contagious diseases" which "propagated to a distance through the air," and "in a hidden fashion silently multiplying themselves by a kind of generation . . . spread destruction far and wide among man and beast."

Skoda of Vienna, inspired by the theory of Semmelweis that poisonous animal matter was introduced by the hand of the accoucheur into the genital tract, suggested to Semmelweis in 1849 that the problem should be investigated by experiments on animals. By means of a brush at first, later a syringe, exudate from a case of endometritis, or pus from an abscess, was introduced into the vagina and uterus of rabbits recently delivered. Later the post-mortem appearances were studied, but in the absence of microscopical examination nothing of real value was learnt.

The Indictment of Bacteria

It was Louis Pasteur who initiated the investigations which were to lead to the indictment of bacteria or microbes as the long-desired *materia peccans* of contagion. The study of diseases of grapes, of silkworms, of cattle, had fired his imagination to "arrive at the knowledge of the causes of putrid and contagious diseases" in human beings. After investigating septic cases in the surgical wards of hospitals he studied cases of puerperal infection in the Maternité, finding in certain of them "a microbe in the shape of chain or chaplet, which lent itself very well to culture."

The description by Monsieur Roux of an occasion (March 11, 1879) on which Pasteur proclaimed this discovery is well worth recalling to our minds. "One day, in a discussion on puerperal fever at the Academy, one of his most weighty opponents was eloquently enlarging upon the causes of epidemics in lying-in hospitals: Pasteur interrupted him: 'None of those things cause the epidemic; it is the nursing and medical staff who carry the microbe from an infected woman to a healthy one.' And as the orator replied that he feared that microbe would never be found, Pasteur went to the blackboard and drew a diagram of the chain-like organism, saying, 'There, that is what it is like!'"

He had found streptococci in the lochia of dying patients and had cultivated them from the blood, taken both before and after death. This was a discovery which must have undermined the opposition of any remaining anti-contagionists, and one can appreciate the satisfaction with which Oliver Wendell Holmes, writing to Dr. Chadwick in 1883 on the contagiousness of puerperal fever, is able to boast: "But I shrieked my warning louder and longer than any of them, and I am pleased to remember that I took my ground on the existing evidence, before the little army of microbes was marched up to support my position."

The new science of bacteriology thus arose, and was ardently pursued by a rapidly increasing army of investigators in all civilized countries. Other organisms were discovered, isolated, and proved to be the cause of rarer types of puerperal infection, most of which were much less severe and less frequently fatal than that caused by the streptococcus.

It is impossible, and really unnecessary for my purpose, to review the story of the discovery of these various organisms. This was admirably done by Arnold W. W. Lea (1910), also a member of the surgical staff of St. Mary's Hospital. The list he gives still stands: in

Side hospital. The epidemic ceased abruptly and we have had no trouble in this regard since.

"I immediately instituted rules and regulations regarding talking on obstetric cases (such as averting the face when talking over a patient so as not to spit upon her, keeping the hands away from the face and mouth while on duty so as not to infect them with saliva, not to attend a labour case if suffering from a head cold or sore throat, etc.), but I do not remember that I insisted on masks.

"The first record that I have of the use of masks is in 1907 while I was preparing the third edition of my book on obstetrics for nurses, which was published in 1908. There is a picture in this book of the doctor aiding the parturient to bear down, and he wears a face mask."

The first protection used by DeLee was "a thick scarf of cheese-cloth." Finding that spittle could be driven through the mesh of this he used thick towelling, and this again he fortified with a four-inch square of adhesive plaster during epidemics of colds or if he himself had a sore throat and had to continue at work.

Kanter and Pilot (1924) appear to have published the first account of a bacteriological investigation of the likelihood of droplet infection in obstetrical practice. It was carried out in the extern department of the Presbyterian Hospital, Chicago. They found "no evidence to support auto-infection from vaginal streptococci," but concluded that "droplet infection from attendants is possible and that the use of masks during delivery and the exclusion of those having sore throats from the delivery room and from attendance on puerperal women is clearly indicated."

Delay in the Use of the Mask

Apart from its use in Caesarean section there has been an astonishing delay in the employment of the face mask in hospital and, even more so, in domiciliary midwifery practice. It is sad to reflect that its adoption or more rigid use in this or that institution, on this or that maternity district, has so often been and still is the direct consequence of an epidemic, more or less rapidly controlled, in the hospital itself. "It would appear that some even await the stimulus of legal proceedings.

Investigation into Hospital Epidemics

Many such epidemics have been laboriously investigated by bacteriologists especially skilled in the recognition of the various types of streptococci. It is only in this way that the origin or the originator of the epidemic or of the sporadic case can be detected and indicted with a degree of probability almost amounting to certainty. The first of these thoroughly investigated epidemics was that which occurred in the Sloane Hospital, New York, in January and February of 1927. Of 163 delivered women twenty-four (15 per cent.) developed haemolytic streptococcal infections; eight of these died. It was fully reported in the August number, 1928, of the *American Journal of Obstetrics and Gynaecology* by Professor B. P. Watson and Dr. Frank Meleney. A complete bacteriological examination of the hospital failed to demonstrate haemolytic streptococci in the air, on the floor or walls, in the operating room, in dressings, supplies, or water. The only place where streptococci were found, other than in the infected patients, was in the nose and throat of certain doctors, nurses, and members of the domestic staff. In the summary of these papers it was laid down that it is "important to exclude streptococcal carriers from maternity hospitals and to insist on complete masking by all in attendance on parturient and puerperal women." Thus one result of

this epidemic was the much more rigid masking of both mouth and nose.

The Sloane Hospital Report aroused widespread interest in a source of infection which, as we have already seen, had been suspected by a few for years but had never before been strongly attested. The report was reviewed and warmly welcomed by Professor DeLee in the section of obstetrics of "The Practical Medicine Series" for 1928. At last he had powerful scientific support for the complete masking of mouth and nose, which he had already been employing and advocating in midwifery practice—against much opposition—for no less than twenty years.

In June, 1929, Nixon and Wright reported two fatal cases of pneumococcal septicaemia during the puerperium from University College Hospital, London. The second patient was a hospital "district nurse." By serological tests it was found that the throat of one of her attendants (who was suffering from a severe "cold") yielded pneumococci of the same type—Type I—as the vagina, uterus, and blood of the woman. This is, I believe, the first case recorded in which the bacteriological evidence attained such a degree of probability. As a consequence face masks, which had been used at deliveries within the hospital since early in 1927, were made compulsory on the district.

Just one more instance of a compelled change of policy. In the early months of 1936 one of the most famous maternity hospitals in the world, the Rotunda (see Annual Report), experienced an epidemic of streptococcal sepsis; four out of fourteen cases ended fatally. This coincided with a severe outbreak of streptococcal throats among the hospital staff and in the city. A full investigation was made, and among the conclusions we read: "Up to this time masks had not been used in the maternity department, but this epidemic and the knowledge of the mode of origin decided a change of policy."

Other Investigations

Many similar investigations have been made since 1928. It is impossible to enumerate or analyse them. However, I believe that all authorities would wish to give a special recognition to the work of Dr. Leonard Colebrook. In a chat with Professor DeLee in Chicago last autumn I was asked to convey the Professor's personal gratitude to "the Colebrooks" for their work on the sources of infection in puerperal sepsis. Dr. Leonard Colebrook has summarized this work; referred freely to that of others; and given his own conclusions in *The Prevention of Puerperal Sepsis*, published in 1936. This should be carefully studied by everybody—midwife, accoucheur, and administrator—concerned for the safety of childbirth.

In 1925 puerperal sepsis was the chief subject for discussion at the British Congress of Obstetrics and Gynaecology, held in London. The possibility of droplet infection was not even mentioned. Professor Whitridge Williams, who took part in the discussion, was impressed by the fact that in a series of streptococcal infections in his service 30 per cent. of the patients had had spontaneous labours without even a vaginal examination: this is a generally accepted proportion. He thought that all bacteriological evidence pointed to the rarity of endogenous auto-infection—all recent work has supported this view. After stating that there must be "some form of external infection which escaped recognition" he drew attention to the possibility of parturient women conveying the organisms on their fingers to the vulva or vagina. This is a danger well recognized by the supporters of

Flügge, reported in 1895. Flügge had not only proved that the micro-organisms found in the human mouth might be pathogenic, but had demonstrated the "surprising and extraordinarily important fact" (to use Hübener's own words) "that when speaking, coughing, and sneezing a spreading about of the mouth and nose secretions takes place. Even at a distance of several metres he had shown that agar plates were covered with colonies after somewhat louder and livelier speaking." Flügge urged the exclusion from aseptic operations of all persons suffering from acute catarrh.

Mikulicz, searching for an "absolutely germless" surgical technique and at this time experimenting with sterilized thread gloves, was deeply concerned by this newly recognized source of infection. He immediately set to work to parry it. In July, 1897, he described the "Mundbinde" (mouth bandage) which he was using for this purpose. This is, I believe, the first publication on the subject. The material used was the finest mull, "sterilized of course," he says, and "fastened to the similarly sterilized operation-gown."

Although Mikulicz claimed that he had quickly become accustomed to their use and "could breathe through them as easily as a lady who in the street wears a veil," we find that he had asked Hübener to search, by experiment, for a comfortable as well as a secure means of protection. In his lengthy paper Hübener describes his method of experimentation. An assistant whose mouth had been thoroughly rinsed with a diluted culture of *B. prodigiosus* spoke and coughed, at varying distances and angles, over appropriately arranged agar plates. The green colour of the prodigious colonies made it easy to distinguish the germs "spoken out from the oral cavity" from those deposited from the air.

Evolution of the Face Mask

These experiments led to the gradual evolution of a metal frame—a modified Esmarch chloroform mask—with spectacle ear-pieces, carrying a double layer of close-meshed mull. As evidence of the exhaustive character of these pioneer experiments it must be noted that Hübener demonstrated that the mask should be held at a distance of a few centimetres from the mouth, and this not for comfort only but to increase its efficiency as a filter. This is a requirement which is ignored in most types of mask, but it can be easily achieved by giving a snout-like projection, by means of a stiffened dart on each side of the simple oblong of folded gauze so much in use.

Concurrently with the investigations of Mikulicz and Hübener the problem was being studied in Paris. The famous surgeon Paul Berger read a paper "On the Use of a Mask in Operating" before the Surgical Society of Paris on February 22, 1899. He began with the statement: "For several years I have been worried as to the part that drops of liquid projected from the mouth of the operator or his assistants may exercise on the outbreaks of infection which one still sees from time to time under conditions of surgical asepsis which are apparently satisfactory." Berger's suspicions had been aroused by the association of a short series of cases of suppuration in clean operations with an assistant who was suffering from an alveolar abscess. The same mishaps occurred several months later, when he himself was suffering from a dental periostitis. His attention directed to the point led him to notice that drops of saliva were projected from the lips of the operator or his assistant even when isolated words, orders in monosyllables, were given.

Aware of Flügge's discovery of the presence of pathogenic bacteria in the saliva, he had set to work to find a means of "shielding his operation wounds from this cause of contamination," even before Mikulicz had published his paper. In October, 1897, he began to wear a rectangular compress of six layers of gauze, sewn at its lower edge to his sterilized linen apron (he had a beard to safeguard) and the upper border held against the root of the nose by strings tied behind the neck. His investigations appear to have been purely clinical, but in the course of fifteen months he convinced himself that he had markedly diminished the incidence of sepsis after clean operations. His paper ends thus:

"It is exactly because I realize that perfection in the carrying out of operations aseptically must not concern itself with any one point but with all, and must neglect no detail, that I have been so anxious to insist on a precaution, the use of which has contributed not a little to improve my operative results. I do not blind myself to the fact that this is too great a shock to custom for it to receive a much more favourable welcome than that accorded by the German surgeons to an analogous communication by Professor Mikulicz."

His surmise was correct: in the discussion that followed a Monsieur Terrier scoffed at the proposal, saying, "I have never worn a mask, and quite certainly I never shall do so." However, in time surgeons did adopt the precaution, and probably the first English surgeon to insist, in a textbook, on the use of the face mask was that master of operative technique Berkeley Moynihan in his *Abdominal Surgery* (second edition, 1906). He pours ridicule on the scoffers "who claim to be satisfied with their results."

Berkeley and Bonney in their *Textbook of Gynaecological Surgery*, first issued in 1911, after testing by experiment the validity of the danger, stated their conviction that the surgeon and his staff should wear masks. Yet in their work *Obstetrical Emergencies*, even in the third edition of 1921, they do not mention the possibility of droplet infection. This illogical position was indeed shared by all, or nearly all, of us who have during the last twenty years practised both gynaecology and midwifery.

The Pioneer in the Use of the Mask

In seeking the pioneer in the use of the mask in obstetric practice I have come to the conclusion that Professor Benjamin DeLee (known at the moment to the American lay press as "Number One Obstetrician, U.S.A.") is entitled to the credit for this.

Let me tell the story in DeLee's own words, from a recent letter:

"I cannot say just when I first started to use face masks in obstetric practice. I believe it was certainly at the same time, or even before, the surgeons used them.

"Just about the turn of the century we had a small epidemic of puerperal infection among the mothers and the babies at the Chicago Lying-in Hospital Dispensary, the home service, which of course was astonishing.

"On investigation I found that one of the interns, who liked to teach and demonstrate to the students while he was delivering the women, had a slight salivation and little tiny droplets of saliva were present frequently at the corners of his mouth. All of the cases that got sick were handled by this particular intern, and one mother and one baby died of streptococcus infection.

"I made a careful study of this intern's nose and throat and found a short-chain streptococcus. I relieved him from service and gave him a position in the laboratory of a South

of time that has led me to confine myself to this one danger.

The history of the discovery of infections by other organisms—staphylococci, the gonococcus, pneumococci, the *Bacillus coli*, the bacillus of Welch, etc.—and the special precautions required to anticipate and thwart each one of them, are of great interest and importance. It would be folly to neglect them while concentrating on one special danger. The most complete surgical technique is essential in really safe midwifery practice. New knowledge may lead to its modification, and it may be that a future Lloyd Roberts lecturer will find this paper of mine useful in composing his own on "The Rise and Fall of the Obstetrical Face Mask."

A report by the Food Council to the President of the Board of Trade on its inquiry into the costs and profits of retail milk distribution in Great Britain has now been published by H.M. Stationery Office, price 9d. The main objects of the inquiry were to examine the extent and the causes of the differences between the financial results, per gallon of milk sold, of various businesses; to ascertain whether retail milk distributors are, on the whole, making an unduly high rate of net profit or rendering unnecessarily expensive services; and to consider the possibility of eliminating any such services and achieving generally a more economical retail distribution of milk. In its conclusions the Council suggests possible lines of action by which a reduction might be made in the average margin covering the expenses and profit of the distributor, in order to achieve a reduction in the retail price of milk.

THE LYMPHOID TISSUE OF THE ALIMENTARY CANAL*

BY

H. GORDON THOMPSON, M.D., F.R.C.S.

(From the Division of Clinical Research, Henry Lester Institute, Shanghai)

(WITH SPECIAL PLATE)

The lymphoid tissue of the alimentary canal consists of the tonsillar and pharyngeal ring, the Peyer's patches, the vermiform appendix, and the solitary follicles of the large intestine, but in order to come to a proper understanding of these lymphoid foci a few words about the lymphatic system as a whole are necessary.

It is the accepted belief now that in vertebrates the lymphatics form a closed tube system and do not communicate with the tissue spaces, with the serous cavities such as the peritoneal and pleural cavities, or with the ventricles of the brain or the central canal of the spinal cord. The lymphatic capillaries form dense networks in most of the tissues of the body; these unite to form larger vessels, and the largest, the right and left thoracic ducts, empty their contents into veins and contribute various-sized lymphocytes to the blood stream. Moreover, as Drinker and Field (1933) point out, care must be taken to distinguish between true lymph obtained from lymph vessels; tissue fluid, the fluid in the region outside blood and lymph capillaries in the cellular interspaces; and plasma, the unclotted fluid of the blood, which differs markedly from lymph and tissue fluid in protein content and to a less degree in salt content. As Drinker and Field say, "the three fluids should not be confused with one another or with blood serum as is frequently done—particularly by immunologists uninoculated with a physiological conscience."

Moreover, as Maximow (1935) asserts:

"The lymphatic networks are distinguished from the blood capillaries by ending blindly in rounded or swollen ends. This is best seen in the mucous membrane of the small intestines; where a network of lymphatic capillaries or a single blindly ending vessel, the central lacteal, extends in the lamina propria up to the end of the villus. The lymphatic capillaries form expanded networks of considerable size round the solitary and aggregated lymphatic follicles of the intestine. They consist of a single layer of flat endothelial cells. The larger lymphatic vessels have valves and slightly thickened walls containing elastic fibres, smooth muscle, and interlacing collagenous fibres."

Maximow concludes his description of lymphatic capillaries and vessels with the important statement. "As the lymphatics form a closed endothelium-lined system of tubes the tissue juice must pass through the endothelial cytoplasm to reach the lumen of the lymphatics."

But the lymphatic system does not consist only of lymphatic vessels. These have associated with them collections of lymphoid tissue known as lymph nodes—sometimes called lymphatic glands—and also lymphoid follicles, the latter being solitary or aggregated follicles according to whether they are single or gathered into groups.

I do not propose to refer further to the lymph nodes, although their internal structure is very similar to the collections of lymphoid tissue elsewhere, but I wish to

* A lecture given at the Henry Lester Institute of Medical Research, Shanghai.

the theory of droplet infection, and special precautions are laid down to thwart it: precautionary advice; a mask for the woman known to have an infected throat; careful and repeated cleansing of their hands; and, in my own practice, a double clove-hitch on the wrists to prevent the hands of the woman in twilight sleep from wandering to the vulva.

As the experts at this congress were oblivious to the droplet danger it is not surprising that the current textbooks on midwifery contained no reference to it. And yet it would seem that, thinking logically, there is the same necessity for rigid aseptic technique in obstetric as in surgical practice. In the seventh edition (1912) of Hirst's *Obstetrics* the mask is considered necessary in major but not in minor surgery, and not in making obstetrical examinations and manipulations. This fallacious view has been held to a ridiculous extent. I have recently seen a gynaecologist wear a mask in an operating theatre whilst repairing a perineal tear of thirty years' duration, but disdain its use when suturing, in a labour room, a tear sustained ten minutes previously. Thus most of us acted less than ten years ago.

The English textbooks on midwifery were late in drawing attention to the danger. One of the best-known did not refer to it in 1925 in its sixth edition. In the seventh edition of 1931, however, we read that the human throat is the chief habitat of the haemolytic streptococcus, and that masks completely covering mouth and nose should be worn by all who are in attendance on labour and by nurses during the puerperium.

It will be asked: Is there evidence of benefit from the rigid use of these, together with other rational precautions, such as early detection and exclusion with appropriate treatment of attendants who have infected air passages and the immediate investigation and segregation of lying-in women at the onset of pyrexia? It is obvious that the masks must be efficient and that they should be in position before the hands are sterilized and before instruments and other appliances are removed from the sterilizer and laid out ready for use—preferably, indeed, before the labour room is entered.

I believe there is convincing evidence from several maternity hospitals where for the last five years or more there has been thorough bacteriological control of the work of the hospital—both indoor and outdoor. Comparison of the results in these two departments has yielded unexpected figures of great significance.

Dr. Joan Rose of the Elsie Inglis Hospital, Edinburgh, in a second report (1936) on "Bacteriological Control," says: "Observations on the incidence of haemolytic streptococci in lying-in women have been continued over a period of six years. The figures for the past three years show that while the general morbidity in hospital and on districts remains low, the pyrexial rate associated with these organisms is higher on the district than in the hospital."

Dr. R. G. Douglas (1937) states that all these precautions—and he lays great stress on efficient masking—have been rigidly employed at the New York Lying-in Hospital since September, 1932. He shows that the incidence of streptococcal pyrexia was two and a half times as frequent in the home as compared with the hospital deliveries. The same result has been obtained in comparable conditions in the practice of the Jessop Hospital, Sheffield, under the control of two whole-time bacteriologists.

The Report of the Obstetric Registrar of University College Hospital, London, for 1936 records that whilst

two cases of haemolytic streptococcal infection occurred in 348 district deliveries there were no cases among the 1,034 deliveries in the hospital itself.

Dr. Leonard Colebrook reports that during the last five years the risk of developing a haemolytic streptococcal infection has been 30 to 40 per cent. higher for any booked case delivered in her own home than it is for similar booked cases delivered in Queen Charlotte's Hospital, and this in spite of the hospital having to deal with many already infected emergency cases. He continues: "I am sure that whereas the risk of sepsis in well-conducted maternity hospitals is growing less and less, we shall never have adequate control over the manifold dangers of familial infection in the overcrowded houses of the poor. I am glad, therefore," he adds, "to see the tendency for more hospital deliveries, and I think we should encourage and facilitate that movement."

Air-borne Infection in Dust

These results have led Colebrook and others to revive investigations into the possible danger of air-borne infection in dust. That the atmosphere was the chief vehicle of contagion was believed by many a hundred years and more ago. The belief was substantiated when Pasteur showed that the air was populated with microbes which caused putrefaction and fermentation. John Tyndall, the physicist, devised beautiful experiments and apparatus to demonstrate the presence of germ-laden dust in the atmosphere, and thus upset the theory of spontaneous generation. Lister attempted to counter the danger by the use of the carbolic spray, within the range of which surgical operations and even childbirth were conducted. Further bacteriological investigations drew attention away from this to other more frequent sources of infection. But it is our duty to leave no possible source of danger unheeded.

The most recent work on air-borne infection has been carried out by William and Mildred Wells (1936) of Harvard University. The experiments are ingenious and the results impressive. In an air-conditioned room with an air centrifuge respiring at the human rate "sneeze-powder" was projected at will among a group of graduates. Bacterial samples of the air were collected by the centrifuge into blood-agar tubes. These workers demonstrate that "it would seem obvious that under conditions of crowding in enclosed rooms we are breathing one another's nasopharyngeal flora, as we once drank each other's intestinal flora in our water supplies." In searching for means to effect air sterilization they have found that germs are killed by ultra-violet rays. Floodlights emitting these rays are now in use in a corridor of the Children's Hospital, Cambridge, Massachusetts, and in the number of the *Journal of Thoracic Surgery* for October, 1936, there is a picture of an operation being conducted within the range of a battery of these lamps.

Charles White, the founder of St. Mary's Maternity Hospital, keenly alive to the dangers of "the foul and disagreeable air" of many hospital wards, strongly advocated ventilators and "every other assistance for clearing the wards of foul air." He would no doubt be delighted with the modern American air-conditioned hospital ward.

Conclusion

I fully realize that I should be doing a great disservice to a cause which I have much at heart if I left the impression that it is only against streptococcal infections, and in particular against the droplet danger, that I advocate precautionary measures. It is largely a matter

Now in all these places there appears to be a special relation to bacterial infection.

The tonsillar lymphoid ring, as we may call it, is at the entrance to the pharynx, where the path of the food and the path of the inspired air cross one another: in other words, the point where the maximum possible combined air-borne and food infection may occur.

The Peyer's patches begin where the curbing antibacterial action of the gastric juice and the bile begins to lose its power and micro-organisms begin to multiply. The Peyer's patches become more marked in the lower part of the ileum, until in some animals, such as the pig, there is to be found an enormous Peyer's patch about six feet long in the lower portion of the ileum next to the ileo-caecal valve.

The vermiform appendix with its lymphoid tissue is situated at the apex of the caecum at the point where there is probably the greatest stagnation of broken-down food-stuffs and where bacteria are most able to multiply. It is a fact that over 50 per cent. of the contents of the caecum of the rabbit is composed of bacteria.

The solitary follicles of the large intestine, again, are in the place where there is marked fermentation and bacterial action.

Thus we see that in all of these places there is apparently a special relation to bacterial infection. Of course it may be a coincidence, but it is certainly very suggestive.

The Lymphoid Ring of the Throat and Nose

Now let us consider the lymphoid ring at the back of the throat and nose. Here the bacteria are taken in by respiration and food. They are for the most part swallowed and are then destroyed by the acid gastric juice, but before entering the oesophagus they have incorporated with them the salivary corpuscles, which are the lymphocytes discharged by the lymph follicles of the tonsils. Digby suggested that the tonsils and adenoids by inviting a direct local infection possibly protected the body as a whole by conferring a general immunity, and it is true that pathogenic bacteria have been found in the lymphoid tissue of the tonsils and have been traced from this point of entry to the lymph nodes of the neck. But although I am not an immunologist I would suggest that possibly the tonsils act also in a somewhat different way, that the discharged lymphocytes or salivary corpuscles react to the bacterial toxins and supply a dose of immune bodies which are swallowed and absorbed by the alimentary canal and help to establish immunity in this manner. Associated with the tonsillar lymphoid tissue are small glands with ducts opening between the folds. During the act of deglutition the ring of lymphoid tissue is contracted, there is a discharge of mucus from the glands, while the lymphoid tissue contributes numerous lymphocytes to the food mass.

A few years ago it was the fashion for children to have their tonsils removed on the slightest pretext, and I remember that when I was a house-surgeon tonsillectomy for enlarged tonsils, not necessarily septic, was by far the most common operation in a large general hospital; but it is now coming to be realized that healthy tonsils must have some use, and that simple enlargement, so long as it is not causing obstruction to respiration, is due to the response of the body to some lack of hygiene or to some dietetic deficiency. It is now a fact that simple enlargement of the tonsils is fast disappearing in European countries, and therefore careful distinction must be made between slight tonsillar enlargements and septic tonsils which cause much ill-health. Layton (1936), surgeon in charge of the throat and ear department of Guy's Hospital,

writing in the *Lancet* in May of this year and speaking from clinical experience, says that in children under 5 to 8 years of age removal of the tonsils impairs resistance to infection—not to the specific diseases such as diphtheria or measles, but to that of general infections, leading to sore throat and colds, and the appearance of diffuse shotty glands in the neck. He further points out that later on, at 14 to 16 years of age, catarrhal deafness is distinctly more common in children who have been subjected to what he calls "flaying of the pharynx," where tonsils and adenoids are completely removed. Moreover, he points out that in the children of the poor living in less hygienic conditions the results may be very serious, and vary from a fading away of the child for no apparent reason to a chronic nasal catarrh which makes it seem as if the child is never free from a cold. He also adds that it is extremely difficult to cure an otitis media which occurs in a tonsillectomized child. All of these facts support the theory that the lymphoid tissue of the tonsillar ring is associated with the protection of the young subject from bacterial infections and that it is of value in the economy of the growing child.

Lymphoid Tissue of the Small Intestine

Turning next to the collections of lymphoid tissue in the small intestine, we must remember that these are associated with the alimentary canal on the one side and with subserous lymphatic vessels on the other. It has been argued that not only the lacteals but also the lymph follicles are associated with the absorption of fat, and that in the latter case this was largely the work of the lymphocytes; but Yoffey (1932) has reported, as the result of experimental work on dogs after feeding the animals on half a pound of lard and collecting the lymph over a period of eight hours from the thoracic duct, that although this was perfectly white and appeared to contain a large quantity of fat, in no case was the proportion of fat higher than 3 per cent., so this would account altogether for only 6 grammes absorbed via the lymph out of a total fat absorption of 226 grammes. Furthermore, even this small amount of fat was not absorbed by the lymphocytes, which in the thoracic duct are practically all (98 per cent.) small, with only the faintest suggestion of a cytoplasmic ring—and no fat could be demonstrated in the lymphocytes by histochemical methods.

I think we can therefore rule out the suggestion that the lymphoid follicles, either solitary or aggregated in Peyer's patches or the vermiform appendix, have any real function in connexion with the absorption of fats.

Relation to Bacteria

Passing on to the relation of the intestinal lymphoid tissue to bacteria, we find strong evidence of this. We have seen that there is a constant and steady discharge of lymphocytes in two directions: (1) into the alimentary canal, and (2) into the subserous lymphatics and so to the thoracic duct. It has not been possible to estimate the number of lymphocytes discharged into the bowel, but the number of those which pass into the blood stream from the lymphatic system as a whole through the thoracic duct is enormous.

Yoffey (1932) found that in a 10-kilogramme dog, on an average, 25 c.cm. of lymph could be collected hourly from the thoracic duct. This had a lymphocyte count of 10,000 to 11,000 per c.mm. The longest period over which lymph was collected was eight hours—this would give a daily lymphocyte output of 6,600,000,000. But the total lympho-

direct your attention to the follicular collections of lymphoid tissue to be found along the alimentary tract.

All lymphatic follicles are composed of a framework and free cells. The framework consists of reticular fibres and fixed cells, which may be flattened out, and correspond to the endothelial cells lining the ordinary lymphatic capillaries. In the lymphoid follicles they are sometimes called histiocytes, or fixed macrophages, because they may have phagocytic powers. As I have pointed out, the lymphatic capillaries form expanded networks round the solitary and aggregated lymphatic follicles of the alimentary tract, including the tonsils, but there is no evidence that these capillaries are continuous with the spaces in the lymphoid follicles in which the free cells are found. The free cells in the meshes of the framework consist of free macrophages and lymphocytes; the former are formed from the fixed macrophages and are highly phagocytic, while the latter are classified as small, medium, or large.

According to Maximow the primitive reticular cells give rise to the fixed and free macrophages, and also the medium-sized lymphocytes, which are the precursors of the large and small lymphocytes, the small lymphocyte being capable of development into the large, which then divides mitotically and produces small ones. Diagrammatically they may be represented thus:

The difference between the lymphoid follicles seen in the lymph nodes and those found in the lymphatic tissue of the alimentary tract is that the latter do not possess lymphatic sinuses and lymph is not filtered through them. They are provided, however, as mentioned before, with net-like plexuses of wide blindly ending lymph capillaries, which surround their outer surfaces except where the follicles come in close connexion with the epithelium of the alimentary tract.

The lymphoid follicles, both in the lymph nodes and in the lymphatic collections of the alimentary canal, consist of a superficial and a deep layer which tend to merge into one another. The superficial follicles comprise a compact mass of lymphocytes embedded in a cellular and fibrous reticulum, while the deeper layer has an outer dense mass of lymphocytes and a lighter-staining germinal centre. The latter is situated in the centre of the deeper follicle and passes through a series of cyclic changes, during which an intense new formation of lymphocytes is brought about through proliferation of pre-existing large lymphocytes and through transformation of the primitive reticular cells. The deeper follicles also include degenerating cells with a poor affinity for nuclear stains, which we have called debris cells because they appear to contain granular debris and crystals.

Another big difference between the lymphoid follicles in the alimentary canal and those in the lymph nodes appears to be this—that the stream of small lymphocytes which is the end-product of the lymphoid tissue of the alimentary canal flows in two directions, towards the lumen of the bowel (Special Plate, Figs. 1 and 2) and towards the subserous lymphatics (Fig. 3). The greater

part enter the lumen of the gut, whereas in the case of the lymph nodes it is towards the lymph sinuses and efferent lymph vessels and so on to the thoracic duct and the blood stream; and, moreover, it is a characteristic of the epithelium overlying the lymphoid follicles in the alimentary canal, no matter whether it is squamous or columnar, that it is constantly found to be infiltrated with lymphocytes. In other words, there is a definite flow of lymphocytes from the deeper follicles or germinal centres through the superficial follicles, then through the epithelium into the lumen of the alimentary canal. These lymphocytes are amoeboid but not phagocytic. Some macrophages and large lymphocytes are also discharged into the intestine, but these are few in number, for the macrophages and the large and medium lymphocytes mostly remain in the centre of the deeper follicles, forming the germinal centre.

May I request your attention to the lymphoid tissue of the alimentary tract as a whole: first, its development; secondly, its position.

Development of Lymphoid Tissue

It is an interesting fact that the development of the lymphoid tissue of the alimentary canal is associated with early life. For example, the lymphoid tissue of the tonsils first appears in the last month of foetal life, generally reaches its maximal development in childhood, and begins to atrophy about the age of 15. Digby (1919) has pointed out that the lymphoid tissue in the appendix of the rabbit is almost entirely developed just after birth.

In order to confirm this we made a series of microscopical sections of the vermiform appendix of small rabbits from the same litter at different times after birth (immediately after birth and seven days, fourteen days, and thirty days after), and the rapid development of the lymphoid tissue was clearly seen. Now the contents of the alimentary canal before birth are sterile, but soon after birth they become infected, and, as Digby says, "it would almost seem that it required the stimulus of bacteria in the alimentary canal to provoke the development of the lymphoid tissue."

I have pointed out on a previous occasion that in the lymphoid tissue of the rabbit's appendix there are normally found numbers of Gram-positive bacteria, and it seemed to be of interest to know how early in life these were present. In the section made just after birth and in seven-day specimens no organisms were seen. In the fourteen-day sections organisms were found on the epithelial surface, but none in the lymphoid tissue; but in the thirty-day sections they appeared both in the crypts and—although not numerous they were definitely present—in the lymph follicles. It would thus seem that the development of the lymphoid tissue begins slightly earlier than the appearance of the organisms, but that the two are definitely associated.

Position of the Tissue

Lymphoid tissue of the alimentary tract occurs in the following positions:

1. At the back of the mouth and nose, where there is an almost complete ring of lymphoid tissue consisting of the lingual, palatine, and pharyngeal tonsils.
2. In the lower part of the small intestine, as Peyer's patches.
3. In the caecum, as the vermiform appendix.
4. In the large intestines, as solitary follicles.

and deep follicles present. (Fig. 6). This work requires confirmation, but if this is forthcoming it is certainly suggestive as a possible reason for the decline in the protective mechanism of the organism against infection and also for the loss of immunity against bacterial infection in vitamin A deficiency.

Professor McCoy lectured recently upon "Immunity in Helminth Infections," and he stated that an immunity is developed in some way at present unknown while the worms are in the alimentary canal. He demonstrated that the development of this immunity could not be brought about after animals had been for two weeks on a vitamin A deficient diet and before there was time for the development of epithelial changes. May it not well be due to the effect of a lack of vitamin A upon the lymphoid tissue of the alimentary tract?

Commentary.

You may ask why a surgeon should venture into the sacred domain of bacteriology and dietetics; the answer is that I believe that just as you have a recognized department of medicine known as "preventive medicine," so there ought to be an endeavour to establish "preventive surgery." I visualize the time when the physician will try to prevent and even treat his typhoid cases, which after all are probably simply attacks on the lymphoid tissue of the Peyer's patches by *B. typhosus*, and the surgeon will try to prevent an attack of appendicitis, which is probably an attack of septic organisms on the lymphoid tissue of the vermiform appendix—possibly in both cases by a well-balanced diet or by vitamin therapy.

Anyhow, every advance in the science of medicine brings nearer the time when medical and surgical advice will be sought more for the prevention than for the cure of disease; for, as recently pointed out by Sir Robert McCarrison, Medicine is not simply concerned with the cure but still more with the prevention of disease, and we surgeons are quite willing and anxious to do our share in the discovery of means whereby we can beat our scalpels and forceps into forks, spoons, and chopsticks for the administration of a well-balanced diet.

I want to thank Drs. H. C. Hou, F. F. Tang, and Yu-ho for much helpful advice. Mr. Henderson for his painstaking efforts in assisting me in this piece of work, and Mr. R. V. Dent for the photomicrography.

H. v. Heuss (*Med. Welt*, November 6, 1937) describes the effects of the "yellow-cross" poison gas, dichloro-diethyl sulphide. It is lipid-soluble and it impregnates the superficial layers of the skin, reaches the subpapillary blood vessels and their nervous plexuses, and since these plexuses are rich in lipoids it tends to accumulate there. The general clinical picture is somewhat similar to that of Addison's disease. The affected individuals are apathetic and adynamic; they suffer from vomiting and diarrhoea and they lose weight, and some cases may show pigmentation of the skin. The author, therefore, recommends for these cases extracts of suprarenal cortex in combination with glucose administered intravenously or intramuscularly.

THE MODERN TREATMENT OF DIABETES MELLITUS AND THE USE OF ZINC PROTAMINE INSULIN*

BY

F. GRAHAM LESCHER, M.A., M.D., M.R.C.P.

Physician, Derbyshire Royal Infirmary

Until about fifteen years ago the treatment of diabetes mellitus in the young and middle-aged was generally unsatisfactory to the doctor, and often almost cruelly to the patient: carbohydrates, fats, and proteins were progressively restricted as the disease advanced, so that the unfortunate patient eventually existed in a state of semi-starvation, until coma and death released him from his sufferings, usually within two or three years from the time the diagnosis was first made. About the year 1922, however, with the introduction of insulin, the renaissance of the treatment of diabetes took place. Even then the policy was still to limit the patient's diet so that only a minimum dose of insulin was required: for it was then uncertain what the exact effect of insulin would be if given over a long period.

Modern Methods of Dieting

It has been only during the last few years that, as a result of the increasing knowledge of the effect of insulin, gradually more liberal carbohydrate diets have been allowed, and lately, unless the patient be overweight, 150 to 200 grammes or more of carbohydrate per day have been given, with a somewhat restricted amount of fat. It has not been found that the insulin has to be increased to any great extent on this account. I have a patient, a young woman, suffering from a severe toxic goitre with much wasting, together with true diabetes mellitus. On a diet of 300 grammes of carbohydrate with as much fat and protein as she likes, and with sufficient zinc protamine insulin to keep her free from glycosuria, she is improving; so much so that a subtotal thyroidectomy will be possible in the near future.

The advantages of an increased carbohydrate diet are:

1. Patients feel much fitter, both physically and psychologically, as the diet approximates to that of an ordinary healthy individual and is more correctly balanced.
2. Life is made easier for them. The modern diabetic can stay at an hotel, and with care is able to choose his food from the ordinary menu; the child can have his meals at the family table, provided he keeps within his fixed ration of carbohydrates, which is now a satisfying one.
3. The chances of hypoglycaemia occurring, which the diabetic dreads, are much lessened.
4. The occurrence of ketosis is much decreased.

5. It has been claimed that an increased carbohydrate diet with a relative decrease of fat lessens the incidence of arteriosclerosis, which is such a common complication of diabetes in later life. This, however, is too large a subject to be referred to any further here.

The simplest method of arranging the diet for a diabetic is, I find, the Lawrence line ration scheme. The number of black lines to be taken, each containing ten grammes of carbohydrate, is settled for each patient. At first this food is weighed, but later on the patient can guess the amount with sufficient accuracy. The number of the red lines containing fixed amounts of fat and

* The substance of the Presidential Address delivered before the Derbyshire Branch of the British Medical Association, June 23, 1937.

cytes in the circulation in this-sized animal averaged out at 2,000,000,000. It therefore appears, as he pointed out, that all the lymphocytes of the blood are replaced three times daily. He suggests that it is quite likely that the lymphocytes are concerned with the active growth processes of childhood, and that the lymphoid tissues act as a storehouse of primitive wandering mesenchymal cells to supply the various tissues as they are needed. He states his belief that the fundamental problem of lymphoid tissue is concerned more than anything else with the fate of the lymphocyte. What, then, is the fate of the lymphocytes manufactured in the lymphatic follicles of the alimentary canal?

In our own work one of the principal objectives was to discover whether we could confirm a definite migration of lymphocytes into the lumen of the alimentary canal. Accordingly a number of rabbits were operated upon, the vermiform appendix was separated from the apex of the caecum, which was closed with a purse-string suture, and the open base of the appendix was brought to the surface so that its secretion, if any, could be examined. In a previous lecture I reported that we had constantly found the ferment amylase present in the secretion of the appendix, so I will not refer to this again; but the point which I wish to emphasize is the fact that the secretion contained great numbers of lymphocytes, a few large macrophages, and some eosinophil cells. Thus there appears to be no doubt that there is a regular flow of cells from the lymphoid tissue into the lumen of the alimentary canal, and that these cells are almost entirely small lymphocytes. There was no evidence that the lymphocytes were acting as phagocytes, although numerous bacteria were present.

The Reaction to Pathogenic Bacteria

Our next effort was an endeavour to discover what was the reaction of the lymphoid tissue to pathogenic bacteria. For this purpose cultures of two kinds of bacteria were prepared for me by the Division of Pathological Sciences: first, bovine tubercle bacilli; and, secondly, *Staphylococcus aureus*. These organisms were chosen because we needed something which would be readily distinguished from the ordinary flora of the alimentary tract.

In a series of nine rabbits the appendix was obstructed and after a few days' interval the abdomen was reopened; part of the fluid secreted by the appendix was aspirated off and replaced by 1 c.cm. of the culture of tubercle bacilli. After a further interval, varying from five minutes to several days, the appendix was removed and examined, smears were taken, and sections cut of the appendiceal wall. It was found that the tubercle bacilli rapidly disintegrated from the contents of the appendix. In one case acid-fast debris was discovered in the deeper lymphoid follicles; and, in another, acid-fast droplets were present on the surface of the epithelium, suggesting that bacteriolysis had taken place. In a third, acid-fast droplets were found both in and just beneath the epithelium of the mucous membrane. In a fourth case, where the animal was allowed to recover, death took place three months later from generalized tuberculosis. I realize that the number of animals used was too small for any definite statement to be made, but the results are suggestive, first, that bacteriolysis takes place either in the lumen of the bowel or in the lymphoid tissue, and, secondly, that bacteria may pass rapidly through the lymph follicles: they may be phagocytosed by the macrophages, or if the infection is a heavy one may pass on into the subserous lymphatics and thus into the general circulation, giving rise to a generalized infection.

Turning to the injection of staphylococci, a culture of *Staphylococcus aureus* was prepared for me by Dr. Tang. The organisms were killed, and then injected into the lumen of the vermiform appendix, the sacculus rotundus of the caecum, and the small intestine opposite to a Peyer's patch, after these had been closed off from the rest of the alimentary canal. Six rabbits were used, and at intervals of from one and a half to fifteen minutes the appendix, sacculus rotundus, and Peyer's patch were removed for histological examination. In the case of the appendix, sections showed some of the organisms on the surface of the epithelium or passing down the crypts, some just beneath, between or associated with lymphocytes within the epithelial cells, some in the superficial and deep lymph follicles, and a few in the lymph spaces.

We had previously noticed that where bacteria were particularly thick upon the surface of the epithelium there appeared to be a moving out of the lymphocytes through or between the epithelial cells as if to resist, and yet there was in that locality no active phagocytosis, thus confirming the theory that any lymphocytic action must be by bacteriolysis, with the formation and discharge of granules (Fig. 4).

At the same time some bacteria could pass through or between the epithelial cells, enter the lymph follicles, and migrate to the deeper parts, where they are met by the macrophages, a second line of defence being formed by phagocytes. The sacculus rotundus and the Peyer's patch showed similar results, but not nearly so marked as in the case of the appendix.

We have previously noted that in the rabbit the lymphoid tissue of the alimentary canal is normally associated with the presence of Gram-positive bacteria, and our next effort was to try to find where these bacteria came from and whether there were any conditions which affected the amount of lymphoid tissue or the number of organisms present, and so lead to some theories as to the function of the lymphoid tissue or the reason for the presence of the bacteria.

Effect of Vitamin A Deficiency

Accordingly several batches of rabbits were put on to a vitamin A deficient diet. It was obvious that the numbers of organisms in the lymphoid tissue were markedly increased; and not only were they present in large numbers scattered throughout the deeper follicles, but they appeared to be massed in colonies as if they were multiplying locally. Especially was this the case in the lymphoid tissue of the vermiform appendix; it was so to a less degree in the sacculus rotundus, and to a still less degree in the lymphoid tissue of the Peyer's patch, situated a few inches from the ileo-caecal valve.

It was also noted that when the animals had been deprived of vitamin A their lymphoid follicles showed signs of atrophy, and in the later stages, when they had begun to develop signs of xerophthalmia, the lymphoid follicles were represented by only a very thin layer of leucocytes (Fig. 5). This was so marked that it was decided to see whether the readministration of vitamin A would cause a regeneration of the lymphoid follicles. A rabbit was therefore chosen which had been on a vitamin A deficient diet for several months and in which xerophthalmia was well developed. The animal was given a similar diet with the addition of carotene in oil for one week and then killed, and the appendix and other lymphoid organs removed. When the lymphoid tissue was examined it was found that the deeper follicles showed the characteristics of active regeneration, with both superficial

this is that the blood sugar cannot then be controlled during the night. I have not used this method.

The best treatment when a severe hypoglycaemic attack does occur consists of intravenous injections of dextrose, as the patient will be unable to swallow. Improvement will follow, but relapses are apt to occur, and several injections may be necessary before the patient is fully restored.

Conclusions Drawn from the Use of Zinc Protamine Insulin and High Carbohydrate Diets

As it is now some time since the appearance of the original papers describing the action of the less soluble insulins the publication of further information which may or may not support the claims made for them may be considered opportune.

My own experience with zinc protamine insulin is confined to twenty-five patients, all of whom, with the exception of the obese, are taking a high carbohydrate diet and have been carefully stabilized either in hospital or in a nursing home. They are attending the "follow-up department."

I have found it possible to keep all the mild cases of diabetes needing insulin well controlled, in good health, and free from symptoms on one dose of zinc protamine insulin, given once a day before breakfast. In the more severe cases the blood sugar was kept within normal limits during the later part of the day, and also during the night, with one dose each day. But its slow action was noted, and glycosuria invariably occurred after breakfast; this was abolished, however, with a dose of ordinary insulin given at the same time as the less soluble insulin. One case of glycosuria after dinner occurred in spite of a large dose of zinc protamine insulin. However, on adding "insulin retard" to the original dose this disappeared. Two of the patients suffered from hypoglycaemic reactions after exercise, and on this account their blood sugars had to be kept a little raised. They were given enough zinc protamine insulin to keep their blood sugars within normal bounds, and some soluble insulin was also given at the same time. No reactions have occurred since.

Only one patient in this series, a labourer, has suffered from a severe hypoglycaemic attack. He had been stabilized with 50 units of zinc protamine insulin and 12 units of soluble insulin. Some weeks after leaving hospital he was working on a morning shift, and was given a heavier job to do than usual. Soon afterwards he became unconscious and was admitted to hospital. He responded well to intravenous glucose, but relapsed a little later. However, after the third dose of dextrose he completely recovered.

All these patients appreciate the fact that they need only the one injection each day.

Method of Use of the Newer Insulins

When stabilizing a patient suffering from diabetes, and one who has never before received insulin, it is quite safe to begin with a daily dose of zinc protamine insulin of 20 to 30 units, or 30 to 40 in a more severe case. The injection is generally given shortly before breakfast, and this may suffice to control the disease in mild cases.

It is usually necessary, however, to increase the amount of insoluble insulin, and the simplest check at first is the state of the urine, providing the patient has a normal renal threshold for sugar; (an abnormal renal threshold is, I find, quite common in diabetes, even in the young).

The urine is tested every three hours, the patient being told to empty the bladder half an hour beforehand, this specimen being neglected. When the urine is sugar-free the blood sugar may have fallen too low; therefore some periodical blood-sugar estimations are necessary at this stage, the specimens being taken about three hours after the injection of soluble insulin and breakfast; about twelve hours after injecting zinc protamine insulin, when it should be working at its maximum force; and before breakfast next morning, when the effect of the insoluble insulin should nearly have worn off. A blood-sugar estimation is of little use unless its time relation to food and the dose of insulin is known.

One's aim in treating young and middle-aged diabetics is to keep them in good health, with a urine free from sugar and a blood sugar within normal limits. But there are some cases of diabetes—generally severe, especially in young people—in which it is impossible to keep the blood sugar within normal bounds without risk of hypoglycaemia; with these patients the blood sugar is very labile, and they may even alternate between hyperglycaemia and hypoglycaemia on the same dose of insulin. One must be content to let them continue with a somewhat raised blood sugar.

When it is thought desirable to change a patient over to zinc protamine insulin from soluble insulin it is safe to start with the same dose and number of units of the former as the patient was taking of the soluble insulin, but given in one injection. This can be increased if necessary, and a dose of soluble insulin added if there is any glycosuria after breakfast. But one certainly hesitates at present to change over to insoluble insulin the large number of diabetics who are well controlled and in good health with soluble insulin and who do not mind having two injections a day.

In cases of very severe diabetes where there is much ketosis, and also in cases of coma, it has been recommended that the patient should have a large dose of soluble insulin in order to get a quick response, and at the same time an injection of zinc protamine insulin, so that the insulin effect can be prolonged. I find, however, that the best plan is to treat these severe diabetics in the ordinary way with large and repeated doses of soluble insulin alone until the condition has improved, when they can be switched over to insoluble insulin if necessary.

Follow-up of Patients

On leaving hospital, where he has been thoroughly trained to manage his diet and to give himself insulin, the patient must be instructed to see his doctor at regular intervals, or to attend a follow-up department, which should be established at every hospital where diabetes is treated. It is well known that the severity of the disease fluctuates from time to time for better or worse: the sugar tolerance may improve; but after some infection or adverse circumstances, and quite often for no apparent reason, the disease may progress. Therefore the amount of insulin may need adjusting periodically. This is a little more difficult to manage with insoluble insulin than with the soluble. With the latter the patient can conveniently attend the follow-up clinic about three hours after his morning dose of insulin, and the blood sugar can be estimated. This gives an idea as to whether or not the dose is suitable. But the optimum time for estimating the blood sugar with zinc protamine insulin taken once a day is before the morning dose. Patients living near the clinic therefore come up periodically before breakfast and the morning dose of insoluble

protein can be neglected unless the patient is obese, the amount taken being left to him, according to his appetite. Thus there are no difficulties in calculating elaborate diets which many patients in the past never understood.

Action of Soluble Insulin

Insulin has a profound effect in lowering the concentration of the sugar in the blood. How this is done is, however, not quite understood. The time relations of its action and of its duration are fairly constant and do not depend on the size of the dose, though the extent of the fall of the sugar in the blood does. The blood sugar begins to fall within fifteen to thirty minutes after injection; the insulin then acts with its maximum force for three to six hours, and its effect has worn off by the end of eight to ten hours. Practically all young patients with diabetes mellitus, and about three-quarters of the middle-aged patients, need insulin.

Diabetes in young and middle-aged people can generally be controlled during the day with one, two, or even three injections of insulin, but in severe cases the glycosuria usually returns during the night, and ketosis may even occur; and if attempts are made to check the nocturnal glycosuria by increasing the amount of insulin there is a great danger of hypoglycaemia occurring when the patient is asleep.

The New Insulins

It has for some time been realized that for these cases of diabetes in which the glycosuria cannot be controlled for twenty-four hours an insulin whose action will last longer is needed. Although much research had previously been done, it was not until 1934 that Hagedorn in Copenhagen found that if insulin is mixed with a protamine, a special type of protein derived from trout sperm, a precipitate is formed which if injected into the subcutaneous tissues has the same effect as ordinary insulin, but is absorbed more slowly, comes into action later, and is more lasting in its effect. This suspension of protamine and insulin is known as "insulin retard." It is absorbed so slowly that it has no appreciable action on the blood sugar for one and a half to three hours after injection. It exerts its maximum action in from six to ten hours, and this ceases after twelve to eighteen hours.

The most recent advance has been that by Scott of Toronto in 1936. He found that if a trace of zinc is added to the "insulin retard" a yet more stable and less soluble insulin is formed, which if injected subcutaneously after shaking is more slowly absorbed; consequently its effect lasts still longer. It is called zinc protamine insulin. It has no appreciable action on the concentration of the sugar in the blood for three to six hours following the injection, after which it slowly begins to work, exerting its maximum effect in from eight to twelve hours. In moderate doses its action lasts from fourteen to twenty-four hours, and in larger doses it has worn off in thirty hours. In practice, however, the insoluble insulins do not act always quite so exactly: there may be a little variation; they may either come into action a little earlier or their effect may be delayed.

Advantages and Disadvantages of the New Insulins

There are certain advantages, but also disadvantages, in using zinc protamine insulin instead of soluble insulin. The following are the chief advantages:

1. Zinc protamine insulin lowers the blood sugar, and owing to its slow action should control it not only during part of the

day but in most cases during the night also; consequently no glycosuria and ketosis should occur during the night, as so often happens in patients treated with soluble insulin. In many cases only one injection in twenty-four hours is necessary.

2. The high carbohydrate diet can be spread more evenly over all the meals instead of confining the bulk of it to those following the injections of soluble insulin.

3. Owing to the slowness of the absorption of zinc protamine insulin no sudden reduction of blood sugar will take place, so that the not infrequent hypoglycaemic attacks in diabetics treated with soluble insulin occur with much less frequency. This is a great advantage, especially in diabetics in whom exercise is followed by attacks of hypoglycaemia.

4. Patients who have been treated with both soluble insulin and zinc protamine insulin say they have a greater sense of well-being with the latter. Possibly this is because of the better control of the glycosuria, the absence of hypoglycaemic attacks, and the need for only one injection a day.

There are, however, certain disadvantages in the use of the newer insulin:

- (a) Since the less soluble insulin is absorbed more slowly it will take longer to come into action—at least from three to six hours. Thus if it is given before breakfast, as is generally the case, the effect of the zinc protamine insulin taken the previous day will very likely have worn off; if not, then the patient has been given too much, for any post-breakfast glycosuria should not be controlled by the zinc protamine insulin which was given the day before. Consequently, as for three to six hours there will not be enough insulin in the blood stream to deal with the sugar absorbed from breakfast, the concentration of sugar in the blood will rise and glycosuria will occur. In such cases the most satisfactory way of dealing with the difficulty is to give along with the zinc protamine insulin, in the same syringe, a requisite dose of soluble insulin. This will act within fifteen to thirty minutes of the injection, and its effect should last until the zinc protamine insulin starts to act.

- (b) As the newer insulins are less soluble the rate of absorption, being dependent on the state of vascularity of the tissues into which they are injected, may vary a little from day to day, and consequently so may the concentration of the blood sugar.

- (c) It is true that hypoglycaemic attacks are not nearly so common in the cases treated with the less soluble insulins, but when they do occur they are much more severe and dangerous, coming on without warning and taking the form of convulsions or sudden unconsciousness, without any of the premonitory symptoms such as sweating, dizziness, etc. Further, these attacks of hypoglycaemia come on later than do those which are due to an excess of soluble insulin, because zinc protamine insulin takes longer to exert its maximum effect. Thus if an injection is given before breakfast, the attack, if it does occur, will take place some time during the following night when the patient is asleep.

Treatment of Hypoglycaemic Attacks

The important thing is, of course, to prevent these attacks from occurring. The stabilization of a patient with zinc protamine insulin should, with our present knowledge, be undertaken only in an institution where the patient can be under proper supervision and where adequate urinary and blood examinations can be carried out. Any increases in zinc protamine insulin must be made with caution and at not less than three-day intervals. A high carbohydrate diet should also always be given and a carbohydrate meal be taken at bedtime.

To prevent the danger of nocturnal hypoglycaemia it has been suggested that the insoluble insulin be given at night alone, with a carbohydrate meal. The disadvantage of

The patient is placed on a Hawley table and the deformity corrected by the usual Whitman manoeuvres. A radiograph is taken to check the position. While the film is being developed the field of operation is prepared and arranged. A lateral incision about six inches long is made, and the great trochanter and shaft of the femur are reached by muscle-splitting. The director is inserted and laid against the shaft of the femur, its upper end being on a level with the lesser trochanter, or two and a half inches below the tip of the greater trochanter. A long, narrow, straight instrument (I generally use a long Spencer Wells forceps) is passed up along the side of the director and placed against the flat anterior surface of the neck of the femur. The director is adjusted so as to lie parallel to the forceps, and is thus in correct position for both planes of the neck. A Kirschner wire is now laid in the groove on the upper surface of the director (held by the assistant) and drilled in.

A second radiograph is taken to check the position of the wire. A pin is now threaded on to the wire, and rests on the director. A metal hammer is also threaded on and the pin is driven home. The pin resting on the firmly held director obviates the risk of bending the guiding-wire, which many surgeons have reported and which renders it impossible to remove the wire afterwards. The wound is stitched up, and a third radiograph can be taken to check the result.

Results

The accompanying Table gives the results of sixteen cases treated in this way. Eleven have been quite successful and the patients are walking about with normal gait.

Table showing Results in 16 Cases of Fractured Neck-of the Femur

Case No.	Age	Sex	Accident	Operation	Walking	Result
1	18	M	20 10 35	24 10 35	18 11 35	Good. Pin removed 9 3 36
2	60	F	2/12/35	4/12 35	28 12 35	Good
3	56	F	13 12/35	16, 1 36	Pin slipped.	Has firm union $\frac{1}{2}$ in. short
4	57	M	22 12/35	1, 1/36	1-2 36	Good. Pin removed 29 4 36
5	30	M	20 12/35	15, 1/36	6, 2/36	Good. Pin removed 1 7, 37
6	63	F	29 3/36	3/4 36	15 7 36	Good
7	65	F	28 4/36	30 4/36		Died of pulmonary embolism 9 5 36
8	61	F	30 5/36	1/7/36	23, 8/36	Good
9	35	M	6, 5, 35	8, 7/36		14-months-old fracture. Neck absorbed. Pin slipped. Refused further treatment
10	59	F	21, 7, 36	27, 7/36	10 9 36	Good
11	63	F	4, 10, 36	21, 10/36	5, 1/37	Good
12	46	F	4, 11, 36	11, 11/36	18, 12/36	Good
13	42	F	9, 12, 36	22, 12/36	2 2 37	Good
14	44	F	31, 1/37	8, 2, 37	6, 3, 37	Good
15	77	F	31, 1/37	11, 2/37		Died pneumonia 24 2 37. Pin found firmly fixed in head in good position
16	74	F	31, 1/37	19 5 37 10 6 37		Neck absorbed. Pin slipped. Pin reinserted. Walking 8 9 37

some of these cases being of nearly two years' standing. I have removed the pin in three instances, but the other patients are disinclined to undergo the slight operation for its removal, as they have so far experienced no inconvenience from its presence. Of the remaining five

patients, one died of pulmonary embolism on the tenth day, and one, an old lady of 77, of pneumonia on the thirteenth day. In this case post-mortem examination revealed the pin firmly fixed in the head of the bone in excellent position. Had these two patients lived it is fair to presume that they would have shown successful results. Case 3 was a failure as a pinning operation because the pin slipped. This patient attempted suicide and fell from a first-floor window, sustaining a double Colles's fracture and a comminuted fracture of the neck of the femur near the base, from a direct blow on the greater trochanter. She now has firm bony union and can walk any distance, but has three-quarters of an inch shortening. Case 9 came under my care fifteen months after the accident. This patient had been treated unsuccessfully in a Whitman plaster. The neck was absorbed and the head atrophied. The pin worked out of the head. I proposed reintroducing the pin and driving it on into the acetabulum, but the man refused further treatment. The last case was that of a woman of 74 who had sustained a fracture of the neck four months before coming under my care. In her case the neck is absorbed, and in my first attempt the pin did not secure a firm hold of the head. I re-inserted the pin some three weeks later and she is now starting to walk, but it is as yet too early to say how successful her case will prove to be.

Clinical Memoranda

An Unusual Case of Chondrification of the Patellar Ligament

(WITH SPECIAL PLATE)

Although cartilage formation in torn muscles and tendons is fairly common the following case is of interest owing to the extent and site of the chondrification. I am indebted to Dr. Killpack of Haywards Heath for the history.

The patient, a boy 12 years old, had fallen and injured his left knee on June 11, 1937, and was admitted to Haywards Heath Hospital. On examination the patella was found to be dislocated. The outward displacement was easily reduced, but some upward displacement remained. The boy volunteered the information that the left knee had been "large and wobbly" for many years. He later developed an acute tonsillitis, and tonsillectomy was performed on July 7. As his knee was still very painful he was transferred to the Royal Alexandra Hospital, Brighton, under my care.

The radiographic report on the left knee stated that the lower angle of the patella was torn off and had separated for fully half an inch. At operation, on September 8, the patella was found to be quite normal, but the patellar ligament was torn off from the lower border of the patella. Embedded in this ligament was a large cartilaginous mass, which was excised (see Plate). The articular surfaces of the femur and tibia were normal. The patellar ligament was then firmly anchored to the patella and the wound closed. Recovery was uneventful.

The specimen was $1\frac{1}{2}$ by $1\frac{1}{2}$ inches, and consisted of cartilage with a bony centre. Its shape was not unlike that of a normal patella.

Honorary Orthopaedic Surgeon,
Royal Alexandra Hospital.

been previously distributed in smaller doses and on rare occasions: thus in the series of post-mortem reports of twenty-one cases studied by Hoyle and Vaizey (1937) tuberculous meningitis was reported in nine. The case to be described belongs to this group, showing disseminated miliary lesions which in the lungs were distributed in the periphery and along the fissures—an example of the form first described by Pagel as cortico-pleural chronic miliary tuberculosis (op. cit., p. 282), and recently studied by Stefko (1936).

Case History

A male clerk, aged 45, was admitted to the sanatorium on July 27, 1937, obviously very ill, with typical signs of meningitis, and died two days later. In addition to the signs of meningeal disease a pleural rub was heard on the left side of the chest, where the percussion note was impaired. No tubercle bacilli were found in the sputum.

History.—The patient's sister said that he had been in good health until March, 1937, when he had "sciatica," but was well again in April. Early in June he complained of headache, shivering, and severe vomiting, with night sweats, and slowly became worse till admission. A radiograph taken on June 30 showed shadows typical of miliary tuberculosis and obliteration of the left costo-diaphragmatic angle.

Necropsy.—There was moderate wasting. Examination of the brain revealed an excess of cerebrospinal fluid, with congestion of vessels and miliary tubercles in the region of the middle cerebral artery. The left pleura was reddened with vascular injection, and between the parietal and visceral layers were universal fine adhesions easily separable by the hand. Section of the lungs revealed miliary tubercles, but with a special distribution. These tubercles were confined to the periphery of the lungs to a depth of about an inch, and lining the pulmonary fissures in a similar manner. Equally striking were the numerous tiny interstitial emphysematous bullae; they were of varying size, but the largest appeared as a small cavity about half an inch in diameter with smooth glistening walls. The kidneys contained a few scattered miliary tubercles, but the spleen, though softened and enlarged, showed none to naked-eye inspection. A stony calcified mass an inch in diameter was found in the mesentery.

Histological Examination.—The nodules were found to consist of small caseous centres with extensive peripheral proliferation of epithelioid cells, lymphocytes, and fibrocytes. In addition there were areas showing exclusively proliferative reaction in the form of small epithelioid cell nodules surrounded by "collapse induration"—that is, collapsed alveoli with fibrotic interstitial tissue. Histological examination therefore showed that this was certainly not an acute process, but one with a definite tendency towards healing or a chronic course at every individual focus (see Plate).

Commentary

Although the clinical history available and the radiograph seemed to indicate that acute generalized miliary tuberculosis would be demonstrated at necropsy, the actual findings suggest a chronic course of the pulmonary lesions, both from the restriction of the miliary foci to the cortico-pleural area and from their macroscopic and microscopical appearance.

One may ask if the pleura exercises a localizing influence on blood-borne tuberculous lesions, and the frequent involvement of the pleura, in the form of idiopathic pleurisy, supports this suggestion. Another explanation, recently upheld by Stefko, is that the pleural lymphatics may be the path of spread, but a closer connexion of the pulmonary nodules and the pleural lesions than was found in the present case ought then to result. Again, experimental work by one of us has produced a chronic haematogenous lesion of the cortico-pleural area

in rabbits by intravenous injection of virulent bacilli after previous immunization of the animals by infection with living avirulent or killed bacilli; the final distribution of the lesions in these animals was the result of absorption of the more central lesions (Pagel, 1936).

It may also be noted that a radiograph which shows a fine mottling in all fields may be a shadow picture of purely cortical lesions, and in such case a tomographic film might give better diagnostic help; evidence of former pleurisy would stress the need for this extra investigation, since its presence may be an indication of the chronic nature of the miliary disease.

Summary

A case of cortico-pleural chronic miliary tuberculosis is described, with the post-mortem examination. The relation of this condition to other forms of pulmonary tuberculosis is discussed.

FRACTURE OF THE NECK OF THE FEMUR ANOTHER METHOD OF INSERTING THE SMITH-PETERSEN PIN

BY

H. B. RODERICK, O.B.E., M.A., M.D.,
M.Chir., F.R.C.S.

Surgeon and Orthopaedic Surgeon, Addenbrooke's Hospital;
University Lecturer and Examiner in Surgery, Cambridge

(WITH SPECIAL PLATE)

The insertion of a Smith-Petersen pin has now become the accepted method of treating fractures of the neck of the femur; but the best means of inserting it is still on trial. Every surgeon who has to deal with these fractures has evolved his own technique, and the respective advantages of the "open" and "blind" methods have yet to be established. Advocates of both methods claim superiority for the one or the other practice, and until experience has proved either of them to be of outstanding merit for the majority of cases it will continue to be of interest to hear of any method which has been consistently successful in any one surgeon's hands. This being so, I venture to describe a method I have evolved which, although "open," may be described as a compromise between the "open" and the "blind" operations, in that it does not expose the fractured ends, which are still protected by the strong anterior ligament of the hip-joint.

The Technique

For my purpose I have designed a director—made for me by the Medical Supply Association—which when placed against the outer surface of the femur at the correct level gives the angle for the insertion of the pin in relation to the long axis of the bone. The lateral plane is gauged by setting the director-edge parallel to a straight instrument laid along the flat front surface of the neck. This will be made clear by reference to the Special Plate.

Reviews

ORGANIC NERVOUS DISEASES IN YOUNG PEOPLE

Diseases of the Nervous System in Infancy, Childhood, and Adolescence. By Frank R. Ford, M.D. (Pp. 954; 107 figures; 14 tables. 38s.) London: Baillière, Tindall and Cox. 1937.

We have learnt to expect only the best from the Johns Hopkins University, and Professor Ford has not fallen short of the high standard set him by this great medical school. He has compiled a most complete textbook of the organic nervous diseases which beset children and young people. This is more than a compilation however, for although the bibliographies at the end of each section bear witness to the erudition which this volume represents the author quotes his own experience and judgments wherever possible, thus giving a personal flavour which many textbooks of this magnitude lack. Charts, tables, illustrations, and case-histories illuminate the systematic descriptions of the many different conditions that are brought under review.

A complete guide to all modern methods of examining the nervous system is contained in the first chapter. This is followed by a discussion of the clinical anatomy and physiology of the system, and in this chapter is included a most useful description of the embryology, morphology, and clinical physiology of the immature nervous system. Next the pre-natal diseases are dealt with, and here are included all the various congenital anomalies of development which are manifest at birth. The heredo-familial and degenerative conditions follow naturally on this; and the great multiplicity of syndromes which, if they have done nothing else, have enshrined the names of so many distinguished neurologists are set out in order. This leads to the infectious and parasitic invasions of the nervous system, divided into sections comprising virus diseases, bacterial infections, invasions by moulds, yeasts, Rickettsiae, spirochaetes, protozoa, and parasitic worms.

Under the heading of toxic and metabolic disorders involving the nervous system we find described the neurological complications of the exanthemata and other more general diseases, of exogenous poisons, metallic and otherwise, of endocrine and metabolic disturbances, and of dietary deficiencies. Vascular accidents and the effects of abnormalities of the circulation as they occur in young persons are next described, and this section is followed by one devoted to neoplasms and related conditions. Trauma is dealt with both as it occurs at birth and subsequently, and sunstroke and injuries from lightning and electric currents are not omitted from this category. The epilepsies and the paroxysmal disorders of the nervous system are fully discussed, and this concludes the systematic description of the diseases and injuries of the somatic nervous system. A chapter is devoted to diseases of the autonomic nervous system and another to diseases of muscles. Finally there is a very useful chapter on syndromes and symptom complexes, such as cerebral spastic paralyses, spinal spastic paralysis, ataxias, disturbances of speech function, and disturbances of vision.

From the brief indications given above it will be obvious that this work is exceedingly comprehensive, and it must prove a most valuable work of reference for all neurologists, paediatricians, and orthopaedists. To these and all other medical men interested in children it can be most warmly recommended.

ENCYCLOPAEDIA OF MEDICAL PRACTICE

The British Encyclopaedia of Medical Practice, including Medicine, Surgery, Obstetrics, Gynaecology, and Other Subjects. Volume 5. *Endoscopy of Respiratory Tract to Goitre.* Under the general editorship of Sir Humphry Rolleston, Bt., G.C.V.O., M.D. (Pp. 632; 139 figures, 35s. net.) London: Butterworth and Co. (Publishers) Ltd. 1937.

The fifth volume of this impressive work comprises the subjects from endoscopy to goitre. Enteric fever and glandular fever are two of the infectious diseases which are included. The differentiation of groups, the isolation of separate bacteria, and the successful application of the principles of immunity to the problems of diagnosis and prophylaxis, combined with an awakening sense of public duty in providing pure water and preventing the contamination of food, have produced a remarkable diminution in the incidence of enteric fever during this century, and the subject now lends itself to the standard description given by Dr. Lakin. Glandular fever, a comparatively new syndrome, with indefinite grouping and unknown aetiology, needing much more work before its position in the medical textbooks is similarly standardized, receives adequate treatment at the hands of Dr. Letheby Tidy, who has made considerable contributions to its recognition and classification. Glanders is rare; German measles common. Erysipelas is notifiable as an infectious disease: Mr. J. B. Hunter recommends the use of benzenesulphonamide compounds, antitoxin, and general supporting measures as well as local applications. Saturated solutions of magnesium sulphate in glycerin have the additional advantage of the hygroscopic effect of the glycerin.

The various articles on skin affections in this volume are valuable, notably that by Dr. Arthur Whitfield dealing in a general and informative way with eruptions, especially those anomalous and atypical rashes which do not fall readily under the usual nomenclature or correspond with the usual descriptions. Dr. Whitfield's classification should help practitioners to recognize these unusual forms. Skin diseases, though so patent to the eye, are not well understood by men in general practice. The series of contributions to the encyclopaedia will prove very useful for reference. Erythema in its diverse forms may be due to many external and internal causes; the description and classification offered by Dr. R. T. Brain should be most helpful, while the full treatment of fungous diseases presented by Dr. W. N. Goldsmith not only draws attention to the diagnosis of the various forms, but offers many alternative plans of treatment for these conditions which so readily become chronic and form a minor source of discomfort and disability. The articles on diseases and injuries of the eyelids and hereditary diseases of the eye are preceded by a succinct account of the methods of routine examination of the constituent parts of the eye and its media. Several inherited eye defects are known, but recent additions to knowledge make it impossible to accept Mendelian laws as a complete explanation of the facts of heredity, according to Dr. Doggart. Some ocular defects are transmitted as Mendelian dominants, some as Mendelian recessives, and others are sex-linked. A comment on family trees diagrammatically exposed in the male sign is more usually and accurately given by the arrow-head pointing upwards and to the tropical diseases included in this volume filarial infestations—are in the capable tributors from the School of Tropical Medicine.

This volume begins with two satisfactory chapters on endoscopy of the upper respiratory

A Swallowed Pin and a Round-worm

The following case may perhaps be considered interesting enough to be placed on record.

CASE REPORT

The patient, a boy of 8 years, swallowed the sharp half of a collar-pin, and was admitted to hospital an hour or so afterwards. The abdomen was screened immediately, and the

foreign body was seen to lie somewhere in the small intestine. The sharp end of the pin was fixed and immobile, while the other end was noticed to move in a peculiar jerky, to-and-fro fashion which was quite inexplicable.

Laparotomy was performed and the pin located in the ileum. On removal a large round-worm was found to have protruded its head through the hole in the blunt end of the pin to such an extent as to become fixed therein. The peculiar movements of the pin as seen under x rays were thus explained.

I enclose a photograph of the worm and pin as they were withdrawn from the intestine.

I am indebted to Dr. De Souza, who operated on the case, for permission to report it.

Merthyr General Hospital.

R. WALSH, M.B., B.Ch.,
Resident Medical Officer.

Recurrent Hydatid Cyst

The occurrence of secondary echinococcosis following rupture or puncture of a hydatid cyst is well substantiated both clinically and experimentally (Dew, 1930-1), but there do not appear to have been many opportunities, at least in this country, of observing the results of such a process at a second laparotomy in the human subject. In this light the following case of recurrence of hydatid cyst may be of some interest.

CASE REPORT

A woman aged 20 was admitted to a surgical ward in Dundee Royal Infirmary on April 26, 1927, on account of acute pain in the right hypochondrium radiating to the back and right shoulder. A similar attack had occurred three weeks before, and lasted for five days. Both these attacks were attended by jaundice and bilious vomiting. On admission a rounded tumour, tender and freely movable, was palpable below the right costal margin. The pain slowly settled, and on May 10, 1927, laparotomy revealed a cystic tumour in relation to the right lobe of the liver, adherent to the small intestine and to the transverse mesocolon. The cyst was dissected free and excised, but is said to have been perforated during dissection. Recovery from the operation was without incident; pathological examination showed the cyst to be a typical hydatid, with numerous scolices but no secondary cysts.

The patient next came under observation on February 17, 1937; the intervening ten years had been uneventful, save for an attack of urticaria in the summer of 1936. The first unequivocal sign of recurrence was a typical attack of biliary colic, accompanied by jaundice and vomiting, following which she was admitted to Dundee Royal Infirmary. When examined on February 22 she was jaundiced but showed no urticaria and had no itching of the skin. Her temperature

was 96° F. and her pulse rate 66. There was neither tenderness nor muscular rigidity and no general abdominal distension, but a soft rounded tumour was palpable in the right iliac fossa. The patient's general condition was good. Blood examination showed: haemoglobin, 104 per cent.; red cells, 5,300,000 per c.mm.; leucocytes, 9,200 per c.mm. The differential count was: polymorphs, 6,800 (74 per cent.); lymphocytes, 1,288 (14 per cent.); eosinophils, 550 (6 per cent.); basophils, 180 (2 per cent.); large monocytes, 360 (4 per cent.). A radiograph of the lower chest and upper abdomen failed to reveal any cyst.

On March 4 laparotomy was performed by Mr. F. R. Brown, a right paramedian incision being made. The greater omentum was found to be adherent to the abdominal wall and to the lower surface of the liver. A thick-walled ovoid cyst 5 by 3 by 2½ inches was found in the right iliac fossa, and was removed by dissection from the small bowel and ascending colon. A second cyst was observed embedded in the left lobe of the liver, but as access to this from below was poor a transverse incision was made on the left side, just internal to the mammary line and at the level of the tenth rib; two inches of rib were resected and the peritoneum incised to expose the left lobe of the liver. Visceral and parietal peritoneum were sutured together and a paraffin-flavine pack inserted. The abdominal wound was closed. Four days later the exposed surface of the liver was incised with the diathermy knife, and typical hydatid fluid with numerous daughter cysts escaped; a thick yellow lining membrane was extracted and the cavity washed out with 1 per cent. formalin. The cavity was flushed out daily with eusol, first through a rubber tube drain and later through a catheter. Discharge of daughter cysts and bile-stained fluid persisted till May 20; thereafter the wound healed satisfactorily, and had completely closed by July 1.

During the earlier weeks after operation the patient had two febrile attacks, each lasting for less than twenty-four hours. In one of these the temperature rose to 102.8° F.; this was accompanied by a rigor and transient jaundice. Each attack was followed by the escape of a daughter cyst through the wound. On April 24 an injection of lipiodol was made into the sinus: this showed up an irregular cavity in the left lobe of the liver communicating with the bile ducts. A series of films was taken, and lipiodol was seen to have reached the small intestine in one and a half hours. After twenty-four hours no lipiodol was present in the liver. On April 28 a differential count showed only 2 per cent. of eosinophils; and on May 12 an intradermal test with 0.2 c.cm. of sterile hydatid fluid was negative.

The patient was discharged on June 11, free from jaundice and abdominal pain. She has since been seen as an outpatient on several occasions, and the improvement is being maintained.

COMMENTARY

The original source of hydatid infection is obscure; other members of the family are healthy, and the patient has never lived in an area where hydatid disease is common. No dog has been kept in the household.

The main point of interest is the length of time that elapsed between the first laparotomy, at which peritoneal implantation presumably occurred, and the earliest appearance of symptoms of recurrence. Even after ten years' growth the cysts were not of exceptionally large size, a finding which lends support to the view (Madelung, loc. cit.) that in most cases hydatid infection occurs in childhood, the usual lack of symptoms until early adult life being due to the slow growth of the cysts.

methods of experiment and inference illustrated in biological standardization. The book deals with the measurement of hormones, vitamins, and certain drugs, and excludes immunological products. Immunological and non-immunological standardization make one intellectual discipline, but the experimental technique differs so greatly in the two branches that to have dealt with both would inevitably have meant composite authorship. Moreover, the more familiar physiological processes involved in non-immunological standardization make it easier for the non-specialized reader to follow. That a German version is already announced is evidence that this is a book that was widely needed and awaited.

ATLAS OF BACTERIOLOGY

Muir's Bacteriological Atlas. Second edition. Atlas enlarged and text rewritten by C. E. van Rooyen, M.D. (Pp. 90; 83 coloured plates. 15s. net.) Edinburgh: E. and S. Livingstone. 1937.

Richard Muir's bacteriological atlas must be well known to most bacteriologists and students of this subject; the appreciation of his artistry extended far beyond Edinburgh, where he worked. In the ten years since this atlas first appeared the microscopy of micro-organisms has extended beyond the cultivable bacteria to still smaller things—the so-called filterable viruses. At one time the viruses were held to be "ultramicroscopic," but it is now recognized that the larger ones come within the limits of visibility with the microscope; even the student is becoming familiar with their appearance. The publishers have deemed it time to bring this atlas up to date, and Dr. C. E. van Rooyen, the author of the new edition, has revised the text and extended the book by the addition of twenty-six coloured plates. Many of the new plates illustrate the morphology of viruses or the changes they produce in the cells which they infect, and, since Dr. van Rooyen's personal investigations have been largely concerned with the morphology of viruses, he is particularly well qualified for this task. And a glance at these plates, not only those depicting viruses but those also of other micro-organisms—bacteria, spirochaetes, and protozoa—shows that the author possesses considerable skill in the coloured reproduction of microscopical preparations; they stand comparison with Muir's, which is equivalent to saying that they are excellent. The text to Plate LVI on page 58 speaks of the nuclei being "deficient in nucleoplasm which . . . is arranged around the periphery of the cell in a margined fashion." Surely this refers to chromatin, which is margined at the periphery of the nucleus. And Plate LV, depicting the inclusions of herpes, is not above criticism, for the inclusions are more like Type B nuclear inclusions and do not show the margination of chromatin so characteristic of herpes inclusions. However, generally speaking, there is little to criticize in the new edition of the atlas, and Dr. van Rooyen is to be congratulated on the way he has done his work in bringing it up to date.

Notes on Books

Surgical Instruments and Appliances, which first appeared in 1905, was prepared—so the author, Mr. HAROLD BURROWS, informs us in his preface—to assist those upon whom the duty of making arrangements for a surgical operation fall. Such a book is likely to appeal also to students about to present themselves for examinations in surgery. On the whole the ninth edition may

be said to be representative of the instruments and materials in current usage—orthopaedics, obstetrics, otolaryngology, and ophthalmology are catered for as well as general surgery—but certain operations and instruments might well have been omitted or replaced. Perforators and burrs are more often used for opening the skull to-day than the trephine shown, and except for the very rare tumour arising in it the Gasserian ganglion is no longer removed. The use of a coin-catcher and probang (illustrated) with an oesophagoscope seems a little unusual, and page 73, depicting a crushing clamp and instruments used for haemorrhoids, might be taken from a pre-Listerian work. In future editions we hope to see this little book brought really up to date, because there can be no doubt about the need for such a compendium of surgical materials. The publishers are Faber and Faber, and the price is 2s. 6d.

A second edition of *A Surgeon's Pocket Book*, by Mr. H. S. SOUTTAR, has recently been published (Heinemann, 7s. 6d.). Into this volume of less than three hundred pages and of a size that will slip easily into a coat pocket without spoiling the shape of the coat has been compressed in tabloid form a review of the whole of surgery. To the Conjoint candidate who wants to acquire as many surgical facts as possible in the shortest time this little book will serve as the perfect *aide-mémoire*. The author has embellished this new edition with small reproductions of the plates in the new edition of his *Art of Surgery*. The student who uses this pocket book as supplementary to the larger work cannot fail to acquire a comprehensive knowledge of general surgery.

In his monograph *Las Miocarditis* (Buenos Aires: El Ateneo) Professor G. N. MARTINEZ gives a comprehensive review of the clinical and pathological aspects of myocarditis, but does not appear to put forward any new ideas or report any original work. Many photomicrographs and electrocardiograms are used as illustrations. In the section on the nosographic classification of myocarditis more space is given to that of typhoid fever than to those of scarlet fever and rheumatic fever combined, and diphtheritic myocarditis is also rather briefly treated. Such an allocation seems disproportionate to the relative importance of the several types. No attempt is made to present modern work on a problem which is of paramount importance in Europe and North America—namely, the pathogenesis of rheumatic and scarlatinal myocarditis and their relation to streptococcal infection. Diagnosis, prognosis, and treatment are discussed with the utmost brevity.

In *Disease and the Man* (Oxford University Press, 8s. 6d.) Dr. R. F. LAPHAM aims at helping the recently qualified man, who is leaving the well-charted hospital wards for the open seas of practice, where he will encounter entirely different problems. This book is yet another sign of the revolt of the clinician against what he regards as the excessive inroads of the laboratory into his province. "With the ever-increasing delicacy and number of analytical procedures . . . attention shifted . . . and with this shift the patient paled into relatively less and less significance . . . [he] became resolved into isolated and impersonal segments." If the immense gifts that science has bestowed on medicine are fully recognized, protests such as these are not without their use at the present time. They help to keep the balance true. The author reveals himself as full of kindly common sense, but he leaves us with the impression that the American student must be decidedly less sophisticated than his English cousin.

A brief memoir of the late Dr. Cécile Booyen has just been published under the initials F. LeG. C., and copies can be obtained on application to the Secretary of the Medical Peace Campaign, 12, Kent Terrace, Park Road, London, N.W.1, price 6d., post free. A photograph of Dr. Booyen appears as a frontispiece to the memoir.

and of the urinary tract. It is desirable, however, that the modern advances attained by gastroscopy should be dealt with more fully; perhaps the editors envisage a separate article in a later volume. Gynaecological subjects are dealt with by Professor Dougal on affections of the Fallopian tubes, and by Dr. Feldman on deformities of the foetus; and Dr. Russell Brain's account of epilepsy is full and clear. The orthopaedic subjects of diseases and injuries of the epiphyses, and of diseases and deformities of the feet, are capably done, and Sir David Wilkie's article on affections of the gall-bladder and bile ducts is full and informative. Professor Fraser and Sir Thomas Dunhill were the obvious choice of the editors to deal with the present-day position in regard to goitre and diseases of the thyroid gland. Their account of their work together is broad-minded and sufficient in detail, but they would be the last to imply that the present exposition is more than a wayside halt to take stock of the position and plan the survey of extended work in the further fields of interendocrine disturbance.

A noteworthy feature of this volume is the excellence of the articles on psychological medicine. Dr. Charles Myers, dealing with the phenomena of mental fatigue, draws a distinction between mental fatigue as exhaustion and the state of lessened activity known as boredom. Using the physiological data of the spinal-cord reflexes as an analogy, he builds up a theory of cortical and mental fatigue. In the absence of strict knowledge of the causation, but conjecturing that there is a biochemical cause, we at present are driven back upon one common remedy—rest—but this must be coupled with appropriate psychotherapeutic measures. Enuresis has a psychological basis so often that Dr. Moncrieff's article will be of much value to the practitioner, and Dr. Neustatter explains the methods of controlling exhibitionism. Among many useful subjects dealt with, Dr. C. O. Hawthorne's wise words on etiquette and ethics in medical practice can be read and reread with advantage.

THE COSMETIC ART

Manual of Cosmetics. By C. Lazar, M.D. (Pp. 318; 12 illustrations. 12s. 6d.) London: Henry Kimpton. 1937.

For those who are interested in the cosmetic side of dermatology this manual by Dr. C. Lazar will be found quite useful. The author appears to have designed this work not primarily for the medical profession, but for that class of persons, which grows more numerous every year, known as "cosmeticians." He does not content himself with the discussion of creams, face massage, scalp treatment, and the various manipulations to which the beauty parlours of this country usually restrict themselves, but he also gives directions for carrying out numerous procedures of a surgical nature which we like to consider are the prerogative of the medical profession alone. Among other matters Dr. Lazar gives directions for the removal of benign tumours, and he instructs his clientele in the use of surgical diathermy, carbon dioxide snow, the galvano-cautery, and the dental drilling machine.

The dental drilling machine was introduced into cosmetics by Kromayer, and Dr. Lazar recommends it strongly for removing freckles and flat pigmented naevi. A spherical burr is used for this purpose, and he says that if the drilling is carried out slowly it is so painless that it is not worth while using local anaesthetic. He gives very full and explicit directions for carrying out the various little cosmetic operations which he describes, and there is no doubt that many medical men who practise minor

surgery will find useful hints for improving their technique and extending their sphere of usefulness if they peruse the manual. Whether, on the other hand, it is safe to put it in the hands of the cosmeticians for whom it is primarily intended, and who have only very sketchy knowledge of the principles of surgery and the pathological possibilities of the human integument, is another matter. In any case it is quite a useful guide to a subject which, though of increasing importance, is usually neglected in the ordinary textbooks of dermatology, and from that point of view it can be recommended. It is worth reading even by specialists in diseases of the skin, who will find in it many useful hints.

BIOLOGICAL MEASUREMENT

Biological Standardization. By J. H. Burn, M.D. (Pp. 288; 64 illustrations. 21s.) London: Humphrey Milford, Oxford University Press. 1937.

We trust that Professor Burn is unduly pessimistic when in the preface to his book he anticipates a poor circulation. On the contrary, we are inclined to predict that for a book of its kind it will be widely read and appreciated. The subject is one of the really vital and progressive branches of medicine and concerns not only medical workers but also druggists and manufacturers. A great change has taken place in the attitude towards biological standardization during the last ten or fifteen years. In 1920 Ehrlich's unit of diphtheria antitoxin was the only serious therapeutic standard in existence. It is true that work had already started, particularly in laboratories concerned with commercial issue, but it was only when the League of Nations organization came forward to co-ordinate the work and introduce international methods and standards that any real progress took place. Not until 1926 was Magnus's standard for digitalis accepted. It may now be said that every biological substance for which it has been proved possible to find consistent methods of measurement has been provided with an international standard, and further standards will no doubt be adopted as technical methods of measurement improve and mature.

So far as therapeutics is concerned we may well believe that this new attitude will end the age of what might be called "private judgment" in therapeutics. If a therapeutic effect is consistent enough to be of value it should be measurable, and if measurable it should forthwith be measured, whether it be in the laboratory or in the wards. In biological standardization medical measurement has begun in good earnest, and the therapist can now say with confidence to the physicist or the chemist, "Our things may be more difficult to weigh than yours, but we weigh them no less conscientiously." Standardization technique is somewhat intricate both in measurement and in interpretation. The only way to make it understandable to the average reader is to give full detail, and this Professor Burn does without becoming obscure or dull; a little physiology is all that is needed in following even his more intricate experimental procedures.

In the interpretative part of the subject the great change which has come about in recent years has been due to the application of statistical methods. To this Professor Burn devotes three introductory chapters, which may be said to embrace a numerical philosophy of standardization. It would be a mistake for the ordinary medical man to look upon this subject as too technical and specialized to be of any interest to him. On the contrary, we believe that there is no better way of approaching rational therapeutics than by the study of the precise

MATERNAL MORTALITY IN THE U.S.A.

The secretary to the Bureau of Medical Information of the New York Academy of Medicine has assembled, in a handy volume,¹ the result of a number of investigations into the problem of maternal mortality which have been carried out in the United States during the last ten years. One of the most important of these investigations was that undertaken by the New York Academy of Medicine itself, and was the subject of an editorial notice in these columns on March 24, 1934. The inquiry dealt only with the City of New York, covering the three-year period 1930 to 1932; others came from the City of Philadelphia and from fifteen States selected from the Registration Area of the Republic. The greater part of Dr. Galdston's report is devoted to a statement of the facts elicited, and they are presented in clear and simple diction which is singularly free from what might be called obstetric jargon. Avowedly the author's public is the whole people of the United States, and he hopes at once to interest them in the problem and to demonstrate its salient features. His main thesis is that the reduction of their high maternal death rates can only be achieved if the medical profession secures the willing and informed co-operation of the general public, and, in particular, of the average American mother.

Dr. Galdston's survey of the conclusions to be drawn from the above-mentioned investigations is lightened here and there by cogent reflections of his own. In speaking of the "preventability" of maternal deaths he points out that deaths are classed as "preventable if they had had proper treatment and care." Behind "if," says the author, stand all those variants of professional competence in judgment and performance, of professional honour, and of good sense which render all human performances variable and unpredictable. It is essential that these considerations should be known to, and understood by, the public, and kept in mind whenever judgment is passed upon a particular case. The desirable attendant in a confinement, he says, is a "physician adequately trained and experienced in obstetrics . . . and aware of his limitations." This point has been made by others, although not perhaps so trenchantly expressed, yet it must not be forgotten that awareness of our limitations is learned by most of us in the painful school of failure, and, even so, it is learned more slowly by some than by others.

The components of the problem of maternal mortality in the United States are not identical with our own, and admittedly American difficulties are

greater in extent than ours even where they correspond. It would therefore be unneighbourly to set up comparisons which on balance would incline in our favour. The principal points emphasized are familiar enough—namely, that large numbers of women receive no ante-natal care whatever; that the "vast majority" are ignorant of, and therefore indifferent to, abnormal conditions which may arise in pregnancy; that a small number of urban dwellers appear to suffer from an exaggerated fear of the sufferings and dangers of childbirth; that there is far too much "meddlesome midwifery"; and that maternity departments of hospitals are too often inadequately staffed and equipped. Dr. Galdston's view is that these defects can be repaired only by a concerted effort of nationwide extent, in which individuals, groups, and committees must co-operate. Men and women alike must first learn what constitutes good obstetric service; then they will demand it, and demand will create supply. Among the first lessons to be learned by the general public is the fact that "operative delivery undertaken merely to alleviate pain and shorten labour involves increased danger for both mother and baby." It is recognized that the education of the public will call for a sustained campaign, not initiated by a few zealous individuals but organized and applied by the community itself. The process of education should begin in senior schools, where in courses of biology the requirements for safe childbirth could be included as part of the reproductive process. Secondary schools and universities, clubs and welfare societies should carry on the work, and so young men and women when contemplating a family would have a clear idea of the general lines upon which safe delivery may be sought, and would be in a position to exercise a wise choice of hospital or of medical attendant. It is of course recognized that when the public demands better obstetric service the doctors will be expected to supply that service. Among the first steps which should be taken by the medical profession Dr. Galdston puts the provision of adequate facilities for postgraduate study of midwifery, the certification of obstetric specialists by an "empowered body," and the recognition by the average practitioner of his obligation to refer all abnormal cases to specialists wherever they are available. Further, all hospitals should be "listed," and only those which are adequately staffed and equipped should be recognized as suitable for the reception of maternity cases.

If Dr. Galdston's survey is instrumental in stirring the great American public to action along the lines indicated there can be little doubt that in due time their problems will be solved; but it is a long, long trail that they are invited to follow.

¹ *Maternal Deaths—The Ways to Prevention*. By Iago Galdston, M.D. New York: The Commonwealth Fund. London: Oxford University Press. (15s.)

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 1 1938

THE IMMUNITY OF LONDON

At a time when public attention has been focused upon the typhoid outbreak at Croydon, which is just over the London border, it is refreshing to turn to the newly published report of the London County Council for 1936 concerning the public health.¹ The report shows in tabular form the comparative immunity which the metropolis has enjoyed for many years from fevers of the enteric group. During 1936 only 255 cases were notified, although this was an increase upon the figure (187) for 1935, and the deaths numbered thirty-one, together with seven others not actually occurring in London, though they were London cases. During the 'nineties the annual mortality in London from typhoid was round about 0.14 per 1,000 living. During the first quinquennium of the present century the rate fell to 0.08, during the second quinquennium to 0.04, and the fall was progressive until 1923, when the figure stood at 0.01, at which it has since remained. The notifications during the last decade of the nineteenth century were about 0.80 per 1,000 living; with the turn of the century they showed a progressive decrease, uninterrupted by the war, and by 1922 the figure was down to 0.06, around which it has remained, except in 1928, when it jumped to 0.13. In that year 580 notifications were made, but the number has been much less in subsequent years, and the lowest figure (109) was reached in 1934. In the late summer of 1936, 154 cases of typhoid were notified in London during a period of nine weeks. Of these, thirteen occurred among a party of girl guides from the Rotherhithe district who had been staying at a holiday resort on the south coast, and thirty-four of the cases were infected during the outbreak in the Bournemouth area, where the infection was attributed to an unpasteurized milk supply. The seasonal incidence of the London cases, as shown by notifications, was greatest in September and October and lowest in December and February. The cases seem to show no preference for any particular part of London, the notifications being greatest in Wandsworth in the south, Fulham in the west, Hampstead in the

north, and Bermondsey in the east. The ages of the patients were under 5 years in twenty-nine cases; between 5 years and 20 years in ninety-one, and between 20 and 35 years in seventy-seven. Of the deaths (fourteen males and seventeen females) only three were at an earlier age than 15.

The mortality from enteric fever has shown over the course of forty years the same characteristic declining curve as scarlet fever, although, of course, the number of cases bears no relation; there were forty times as many cases of scarlet fever in the metropolis as of enteric, but the mortality from scarlet fever at the beginning of the century was the same as enteric—namely, 0.14 per 1,000 living—and it is now 0.01, the same as enteric. All the infectious diseases in fact show a marked decline. No case of small-pox has occurred in London since the middle of 1934. Deaths from measles (584) were fewer than in the previous epidemic years—1934, 1932, and 1930. Deaths from whooping-cough were higher, being 278 as compared with 166 in 1935, but here again there was a fall as compared with earlier years. Deaths from scarlet fever numbered only forty-two and from diphtheria only 226. The report mentions 382 cases of food poisoning, with one death, during 1936. The majority were isolated cases, and possibly due to the idiosyncrasy of the victims. The foods incriminated were chiefly meat and fish. Three or four outbreaks were said to have been caused by food eaten at staff canteens.

Altogether the healthy condition of London is a matter of legitimate pride, and reflects the greatest credit on the health services and on the medical profession in general. It must be remembered that in the area administered by the L.C.C. and the City Corporation we have a population of over four million persons, of whom one-fifth are under fifteen years of age. They live in three-quarters of a million houses, and one-third of a million people live under overcrowded conditions. Furthermore, London is the port of call for all manner of persons coming from all manner of places. It is constantly the scene of a migratory movement; every year, to judge by the last intracensal figures, nearly 10,000 persons who have been born elsewhere settle in the metropolis—a figure much smaller, by the way, than in years gone by. Yet London keeps resolutely healthy and free from infectious diseases. A cause of mortality which is becoming formidable in the statistics is one which it hardly comes within the sphere of the medical officer to avert. Deaths from street accidents (541 in 1936) exceeded the deaths from influenza and equalled those from diphtheria, whooping-cough, and scarlet fever combined.

¹ Annual Report of the London County Council, 1936. Vol. iii (Part I). Public Health. P. S. King and Son, Ltd. 1937. (1s.)

averages for the previous nine-year period, but the picture presented by these figures would have given readers a false impression of the actual situation. Mere lists of figures, although invaluable in directing attention to the occurrence and prevalence of particular diseases in different areas, give no information about the circumstances in which an outbreak has originated; nor do they reveal the steps which have been taken to control it or the measure of success which has attended them. In the comments at the end of the table we hope to give this information when it is available and when it seems relevant. We would therefore take this opportunity of seeking once more the co-operation of medical officers of health in keeping the medical profession fully informed on epidemic matters. A public health authority, especially that of a health resort, may be faced with an apparent conflict of interests in disclosing information regarding the occurrence of infectious disease in its area, particularly during the holiday season. As a matter of experience outbreaks of infectious diseases rarely arise through the direct fault of local authorities, but should any attempt be made to conceal its presence or gravity, or should there be delay in applying appropriate measures for its control, blame may be attached to those responsible. The policy of administrative candour is bound to pay in the long run. The recent application of the Public Health Act, 1936, makes the present time an opportune one for initiating this weekly survey.

THE CEREBROSPINAL FLUID

Drs. Houston Merritt and Fremont-Smith have already contributed a valuable article on the cerebrospinal fluid to *Nelson's Loose Leaf System of Medicine*, as well as numerous short articles on the same subject. They now give us at greater length the data from which they have formed their opinions.¹ These are taken from the records of the Boston City Hospital, and comprise personal examinations of 21,000 specimens of cerebrospinal fluid taken from patients suffering not only from disease of the nervous system but from many other conditions in which involvement of the nervous system was suspected. Although this wealth of material has not included every known disease which produces alterations in the fluid, it leaves few gaps and gives authority to the statements made. The authors are firm supporters of the "dialysate" theory of the formation of the fluid, though they confess that it is not possible to explain all the phenomena of its composition and formation by this theory. Of its absorption they say disappointingly little, and leave many questions related to hydrocephalus and increased intracranial tension unsolved. The monograph is, however, intended to be practical rather than theoretical, and when viewed in this light leaves little to be desired. Their full survey of the changes in the fluid found in many forms of nervous disease, and the diagnostic implications of the various fluid syndromes, should be valuable to practitioner and pathologist alike.

¹ *The Cerebrospinal Fluid*. By H. Houston Merritt, M.D., and Frank Fremont-Smith, M.D. W. B. Saunders Company. (22s. 6d.)

INDUSTRIAL DERMATITIS

Dermatitis as an industrial disease has developed into an important subject during the last few years. First cited as a ground for workmen's compensation in 1916 owing to the large number of cases arising in the course of munition work, it has since been reported with increasing frequency. As is well known, it is closely related to eczema, and the practical question continually arises whether a patient suffering from an inflammatory condition of the skin is to be considered as a victim of industrial dermatitis, and therefore entitled to compensation from his employer, or of eczema of constitutional origin. The importance of the subject is shown by the fact that not less than 15,000 cases of dermatitis are certified by factory surgeons every year. Dr. MacCormac, in a discussion on the subject at the annual meeting of the British Association of Dermatology, pointed out that the age incidence of idiopathic eczema and of industrial dermatitis, especially in males, is very much the same. He concludes that large numbers of cases of alleged occupational dermatitis are probably idiopathic eczema; though he admits that they may be examples of idiopathic eczema prematurely induced by the occupation of the patient but maintained by the constitutional peculiarity which determines eczema. This is rather a fine distinction and does not alter the legal liability of the employer to pay compensation in such cases. Quite commonly, when the disease first shows itself, the employer agrees to pay compensation, but a legal battle may take place when the employer makes an application to end the compensation on the ground that the workman is no longer suffering from industrial dermatitis. Some medical men are inclined to hold the view that a dermatitis due to work cannot persist for a long period after the removal of the alleged irritant, and that when it appears to do so the patient is really suffering from idiopathic eczema. If this view were accepted by the courts the workman's compensation would be stopped, but, very properly, judges are extremely reluctant to take up this attitude, and they are supported by another body of medical opinion, which holds that the human skin which has once been attacked by occupational dermatitis may acquire a habit of breaking down, and of becoming sensitive to agents and influences which were previously harmless. The beginning of all cases of occupational dermatitis is the certifying factory surgeon's certificate to the effect that the patient is suffering from this condition. This throws the liability of compensating the suffering workman on his employer or his representatives. Although in the vast majority of cases the certificate is correct, it must be remembered that factory surgeons are not often dermatologists, and hence cases occasionally arise in which other skin troubles—for example, lichen planus, psoriasis, or even scabies—are certified as occupational dermatitis. By the regulations governing the procedure under the various Workmen's Compensation Acts any appeal against the factory surgeon's certificate must be entered within ten days, and if this is not done the certificate becomes binding. In this way workmen occasionally draw compensation

DOMINION GRADUATES AT OXFORD

Lord Nuffield, whose gifts to the University of Oxford during the past two years have amounted to just upon three and a half million pounds, has made a further allocation for the special benefit of medical graduates from the Dominions. He has placed at the disposal of the trustees appointed under his benefaction of October, 1936, when he set aside two million pounds for the purpose of the Medical School, a sum of approximately £168,000 in order that graduate students from South Africa, Australia, and New Zealand may have facilities for sharing in the advantages of the developments which are taking place at Oxford. During recent visits to the Dominions—he is now proceeding on another visit to Australia, to attend the 150th anniversary celebrations at Sydney—Lord Nuffield has been impressed by the flourishing condition of the medical schools despite their remoteness from the great centres of research, and it has seemed to him that a scheme which made freer access to Oxford possible for selected graduate students would encourage deserving work and be advantageous both to the Dominions concerned and to Oxford itself. He has therefore offered to establish in Oxford three demonstratorships, to be held in turn in the departments of anatomy, biochemistry, pathology, pharmacology, and physiology, and three assistantships in the departments of medicine, surgery, obstetrics and gynaecology, anaesthetics, orthopaedic surgery, and therapeutics. These posts will be tenable for a fixed period by graduates eligible for or already holding similar positions in those universities of South Africa, Australia, and New Zealand which grant medical degrees. The holders will be selected in rotation by the overseas universities. Payment of a sum for apparatus and incidental expenses will be made to the Oxford departments in which the visiting demonstrators and assistants work. The scheme also contemplates the appointment from time to time by Oxford University of a visiting professor to tour the Dominions for the purpose of giving information with regard to research in the home country and at the same time studying the overseas needs. Lord Nuffield's gifts are of such magnitude that public attention is apt to be drawn to their scale, and the vision which inspires them is overlooked. In this latest gift, the benefactor reveals again his appreciation of a need not previously met and perhaps forecasts a scheme of study-visits and interchange on much bigger lines than this allocation can immediately bring about.

To the British Medical Association, which, especially during recent years, through its

assemblies over-seas, its appointment of delegates on various occasions in the Dominions, its fostering care of Oversea Branches, and the constant work of its Dominions Committee, has done much to establish contacts and to secure for the medical profession in the Dominions a like position to that which has been established in the home country, this scheme will be specially welcome. It means far more than the creation of a few temporary appointments at Oxford. The Dominions themselves will benefit from the experience of these graduates on their return, and the spirit and technique of medical research and education as carried out under the most authoritative auspices will permeate the medical schools in the newer lands. As everybody knows, some very noteworthy contributions to medicine have come from the Dominions, but the relative isolation of the universities there has imposed a necessary handicap and has made certain inequalities inevitable. A reciprocal advantage will be that the University of Oxford itself, in its Nuffield School, will benefit by the presence of highly qualified workers, who will bring to the laboratories and wards the freshness of outlook and impatience of convention which one associates with our kinsmen from other parts of the Empire. The Oxford medical school will never forget that one of its most distinguished regius professors, Sir William Osler, came from over-seas.

A WEEKLY EPIDEMIOLOGICAL SURVEY

To give readers some idea of the extent and prevalence of notifiable diseases we print this week at page 52 a table under the heading "Epidemiology and Vital Statistics," and intend to include this from now onwards as a regular feature of the *Journal*. We shall supplement this when occasion demands with brief comments on any significant feature of the table and on any matter that is of current epidemiological importance. The table is compiled from the Registrar-General's weekly returns and from similar returns that have been made available to us through the courtesy and co-operation of the Departments of Health of the Irish Free State, Northern Ireland, and Scotland: to them we are much indebted. It should be made clear that the figures in this table do not apply to the week immediately preceding the issue of the *Journal* in which they appear but to the penultimate week—the latest period for which the information is available for publication in these columns. Attention is also drawn to the fact that the figures for the deaths under the heading of each infectious disease are for a certain number of towns in each area, while the figures for the notifications are for the whole area in each case. This is made clear in the legend at the head of the table. It will be noticed that median values can at present be obtained only for a limited number of notifiable diseases in this country and in London. It would have been a simple matter to give a list of

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

THE TREATMENT OF BURNS AND SCALDS

BY

PHILIP H. MITCHINER, M.D., M.S., F.R.C.S.

In dealing with the treatment of burns and scalds in general practice one of the most important things to realize is the far better prognosis which can be given in the case of scalds than in the case of burns. For whatever the treatment used, it is a well-established fact that the mortality rate in scalds is only one-third of that from burns, and therefore in any scald a correspondingly better prognosis can be given than in a burn of the same extent.

Why do Burnt Patients Die?

One of the first things to remember is the importance of prophylaxis, and in order to apply this effectively it is necessary to understand the causes which result in the death of the patient. It has been established that 80 per cent. of the deaths ensue from shock and collapse, which are due partly to the absorption of histamine and other toxic bodies from the damaged tissues, partly to the excessive loss of fluid from these tissues, and, lastly, to the pain from the exposure and stimulation of nerve endings. The remaining 20 per cent. mostly result from sepsis, and occur not within the first two days as in the case of the collapse, but in about a week or ten days from the infliction of the burn.

Discussion of the researches which have led to these findings is out of place in such an article as this, but those who wish to inform themselves of the details are referred to the many works on the subject. It will be seen from the above that for any treatment to be efficient it must be directed primarily to the avoidance of collapse and must aim essentially at the complete coagulation of all damaged tissues in order to prevent the absorption of toxins, the escape of fluids, and excessive pain. Secondly, thorough cleansing of the damaged area and its surroundings is necessary if sepsis is to be avoided. By the thorough application of these two principles, coagulation and cleansing, the modern treatment of burns has been able to show such a great advance that the mortality from these injuries has dropped to one-tenth, as will be seen by the study of Table I.

TABLE I.—*Mortality of Burns and Scalds in St. Thomas's Hospital*

Year Groups	Treatment	Mortality (per cent.)	
		Burns	Scalds
1894-1895	Baths and ointment	39.6	18.8
1900-1903	2 per cent. picric	39.7	7.0
1924-1928	2 " " "	15.5	7.5
1929-1936	2 per cent. tannic	4.0	1.7

Coagulant

It is essential that to be efficient a coagulant should be able to penetrate while acting, so that the entire depth of damaged cells may be reached. There is otherwise

a grave danger that a superficial coagulum (which still permits of absorption and escape of fluids from the deeper uncoagulated tissue) may lead to a sense of false security through having caused cessation of pain and a temporary improvement in the patient's condition—an improvement which is not maintained but is succeeded in a few hours by the advent of that "secondary collapse" so well described by Wilson of Edinburgh and so frequently fatal. It will be seen that the ideal coagulant not only should be capable of penetrating but it must be used in a solution weak enough to allow it time to penetrate into the depths of the damaged tissues. As the mortality table shows, the use of picric acid led to a fall in mortality; this was due to its coagulant properties, but no greater fall occurred, because picric acid coagulates only the superficial tissues. Tannic acid, on the other hand, if used in a sufficiently weak solution, is capable of penetrating through the entire depth of the damaged tissues, and therefore gives far better results than either picric acid, silver nitrate, or strong solutions of tannic acid, which produce only a superficial coagulum.

The older methods of treatment by ointments or paraffin-wax merely secured cessation of pain and in no way procured coagulation, so they will be mentioned merely to be condemned. Similarly the modern method of treatment by crude cod-liver oil preparations offers in its results no comparison with those obtained by coagulation, though it has the advantage over the older greasy dressings that sepsis can be held largely in check. The gentian-violet treatment also aims at antiseptics, but it does not produce coagulation, so that the results are not satisfactory in severe burns, though considerable absorption of the dye occurs.

The Use of Tannic Acid

One important point in relation to tannic acid is to remember to use weak solutions. Personally I advocate a 2 per cent. strength—certainly never over 5 per cent. It must be borne in mind that tannic acid in solution readily grows a large selection of moulds and thus becomes very septic; so an antiseptic has usually to be added to prevent this. Various antiseptics have been tried, the most successful being perchloride of mercury 1 in 2,000. It has been found, however, that this solution decomposes in about two months, and in order to prevent this a powder is used which not only keeps indefinitely but dissolves easily in warm water. This consists of tannic acid, 17½ grains, and perchloride of mercury, 1/2 grain, to be dissolved in two ounces of warm water. This gives a 2 per cent. tannic acid solution with 1 in 2,000 perchloride of mercury; and the two ounces, in addition to being sufficient for each spraying, will soak a compress dressing 6 by 4 inches, which is large enough to cover the average burn met with in domestic practice. In the case of larger burns two or more powders, as may be necessary, can be dissolved in a corresponding quantity of water. As the perchloride, however, has the disadvantage of being scheduled as a poison, many other antiseptics have been tried, including acriflavine and hexyl-resorcinol, of which the latter in a 1 in 2,000 solution is the most beneficial. These, however, frequently cause pain to the patient and interfere with the formation of a hard and

which they really do not deserve, but such cases are very infrequent. On the whole the Act carries out the intentions of the legislature satisfactorily. Many modern industrial processes entail serious risk of damaging the skin of the workman, and, although cases of industrial skin disease form only a small percentage of the accidents and diseases to which workmen are liable in the course of their employment and for which it has been rightly decided that they should be compensated, the actual number of skin cases is, as we noted above, by no means inconsiderable. It must be remembered not only that there are many branches of manufacture in which the skin is exposed to various sorts of liquids and dusts which are notorious for their liability to damage the skin, but that most manual labour is carried on under rough and dirty conditions which are likely to be detrimental to any skin insufficiently endowed with toughness. The number of cases reported has much increased during recent years. This is not due to any deterioration in conditions of work, but is because the approved societies have woken up to the opportunity open to them of getting rid of their liabilities to their members in respect of skin disease. At the present time, whenever a workman goes sick with any form of skin disease his approved society is extremely likely to attempt to show that it is a case of industrial or occupational dermatitis. Most of these cases are settled on reports from the medical men who advise the insurance companies which relieve the employers of their statutory liability, and the number of cases which ultimately find their way before a legal tribunal is very small. On the whole, though occasionally abused, the law providing for compensation in cases of industrial dermatitis works well and protects the interests of the worker in a just and satisfactory manner.

CO-OPERATION BETWEEN PHYSICIAN, SURGEON, AND DENTIST

From the Editor of the *Military Surgeon* we have received a reprint of a paper on the interrelation of medicine, surgery, and dentistry in military and civil practice read by Captain W. S. Bainbridge of the U.S. Naval Reserve Medical Corps-Fleet. He urges closer co-operation between physician, surgeon, and dentist, and supports his argument by interesting and pertinent cases met with in his own practice, and by observations from outside it. Hippocrates 2,500 years ago cured a patient of rheumatism by removal of a diseased tooth. In the world war bone wounds among Mohammedan regiments healed badly till orange sticks were substituted for tooth-brushes—unused on account of a possible pig-bristle. In Captain Bainbridge's practice contact between dissimilar metal fillings has been found capable of causing lesions of cheek or tongue suspicious of malignancy; the lesions were cured by insertion of similar metal fillings; and mastitis has been found definitely dependent on dental sepsis. Reading the detailed clinical cases gives us the impression that actinomycosis of the mouth is far commoner in the United States than in this country. The author most certainly proves his thesis.

THE TRUDEAU FOUNDATION

To those familiar with the development of the sanatorium movement the name Trudeau probably conjures up the picture of a young married man with advanced pulmonary tuberculosis, almost given up by his physicians, trudging along the Adirondack Mountains, an isolated spot in North America, in the hope that the open-air life would work a miracle. That was over fifty years ago; and the miracle happened. To most people, however, the name Trudeau brings to mind the Trudeau Foundation at Saranac Lake, with its modern sanatorium of 185 beds and laboratory, also a special research laboratory and medical school for tuberculosis, which were established in 1916 to Trudeau's memory—all at the spot to which he came to regain his health. It is now over twenty years since Edward Livingstone Trudeau died, but the yearly reports of the Trudeau Foundation continue to bring before us the results of his work and vision. The sanatorium caters for "self-supporting" people; the Trudeau School of Tuberculosis gives courses of instruction to physicians, and by awarding fellowships for study and research provides support for young physicians and scientists undergoing treatment. There is a clinical research laboratory at the sanatorium, and, in addition, in the village of Saranac Lake, there is the Saranac Laboratory for the study of tuberculosis, formerly the private laboratory of Dr. Trudeau, which, though co-operating with the sanatorium laboratory, is a separate concern. It serves as headquarters of the Trudeau School of Tuberculosis, provides diagnostic facilities for the physicians practising in the village, and carries out independent researches in the field of tuberculosis and associated conditions. The annual report for 1936,¹ consisting of three pamphlets, has just reached us. The general report, which is concerned chiefly with financial details, is of less interest to clinicians than the medical one. Some of the results published in the latter are worthy of note. During the year 264 patients were discharged (including three deaths), but sixteen of these were either non-tuberculous or only suspected of having tuberculosis. "Only sixteen, or 6.5 per cent., of the remaining 248 were discharged as having their disease 'arrested,' and twelve, or 5 per cent., as 'apparently arrested,'" the report stating that "the few months' residence for most patients is insufficient for complete arrest." This comment must be amplified by giving some further figures. Of the thirty-eight patients who stayed from thirty to ninety days (average sixty-two days) 23.7 per cent. were discharged as "quiescent"; of 187 patients who stayed ninety days or over (average 299 days) 15 per cent. were discharged as "arrested" or "apparently arrested," and 50.2 per cent. as "quiescent." Among these 187 people no less than 63.6 per cent. were classified as "moderately advanced" and 12.3 per cent. as "far advanced" on admission. While the report does not indicate how far the terms used at Saranac Lake are comparable with those in this country, the results would appear to be better than those obtained in sanatoria of a similar type here.

¹ Report of the Trudeau Foundation for the year ended September 30, 1936.

satisfactory coagulum. It cannot be too strongly impressed on the practitioner that the addition of this antiseptic is to preserve the tannic acid solution, and does not prevent sepsis in the area of the burn, which must therefore be most carefully cleansed, as described later.

After these preliminary remarks I will proceed to consider in detail the treatment with tannic acid. This may be applied by either the compress or the spray, but inasmuch as the spray treatment is possible only in hospital it will not be described here: experience shows that it never gives good results in severe burns when applied under the conditions of private practice, and it is unnecessarily complicated in slight cases, where the compress or the application of tannafax jelly gives equally good results. In passing, it may be mentioned that tannafax jelly is an excellent method for treating small burns such as so frequently occur in homes, where it can with advantage be kept with the stock of first-aid applications. It does not, however, give satisfactory results in large or extensive burns. (A full description of the spray method can be found in *The Modern Treatment of Burns and Scalds*.)

First-aid Treatment

The treatment of burns, as of any injury, resolves itself into first-aid and final treatment. The first-aid treatment must be immediate, because the sooner a coagulant is applied the smaller is the likelihood of collapse. It may be argued that few homes keep tannic acid; but there are very few where tea is not procurable, and the infusion of tea as we drink it contains from 2 to 5 per cent. of tannin—a fact realized long ago by the Chinese, who have successfully dressed their burns with tea for over 5,000 years. All that is necessary, therefore, as a first-aid measure is to soak clean linen in tea and apply it promptly all over the burnt area. Care must be taken that the tea is sufficiently cooled, so that no scald is inflicted by its application.

Oils, flour, and butter must have no place in the first-aid treatment of burns, for, although they stop the pain, that is all they can do, and collapse, often fatal, will occur.

After the application of tea or tannic acid wrap the patient up well and give plenty of warm fluids to drink; an injection of morphine, 1/4 to 1/3 grain, or a dose of tincture of opium, according to the age of the patient, may be given with advantage, and this fact must be recorded. Do not hurry the patient into an ambulance and rush him to hospital; he will be very much better if he is left lying quiet for half an hour before being transferred.

Final Treatment

The final treatment consists in the application of the tannic acid compress; but first the burnt area and surrounding skin must be thoroughly cleansed, and this can be efficiently carried out only under anaesthesia. Burnt patients are liable to pulmonary complications, so that inhalation anaesthesia should be avoided; similarly there is a tendency towards albuminuria, with renal and hepatic inefficiency, and therefore barbiturates such as evipan or avertin are not without their risks. For these reasons heavy dosage with opium or morphine, as suggested in Table II, has been found most satisfactory to induce anaesthesia in these cases. In this respect it must be remembered that the drug will need at least half an hour to act before the patient is sufficiently somnolent to permit cleaning to be proceeded with.

TABLE II.—Opium Dosage for Cleansing Burns and Scalds

1.—IN CHILDREN

Age	Preparation	Dose
1 month	Tinct. camph. co.	℥ij-ij
2 months	" " "	℥iv-ij
3 "	Tinct. opii	℥i-℥
6 "	" "	℥℥-℥
1 year	Tinct. opii (a) or Inj. morph.	℥ij-ij
Over 1 year	Tinct. opii or Inj. morph.	grain 1/75 ℥ij for each year and ℥ij in 15 minutes if necessary grain 1/75 for each year

2.—IN ADULTS

Age	Preparation	Dose
12-15 years	Tinct. opii and Inj. morph.	℥xxx grain 1
15-20	Tinct. opii and Inj. morph.	℥xxx grain 1
Over 20 years	Tinct. opii and Inj. morph. (b) or Inj. morph. (c)	℥xxx grain 1-1 grain 1-1

(a) Tinct. opii is more satisfactory than morphine. (b) For women. (c) For men according to stamina.

N.B.—Should slow or shallow breathing give rise to anxiety atropine sulphate 1/200 to 1/50 grain should be administered hypodermically.

Essential Cleansing

When the patient is well under the morphine the first-aid dressing is removed and the area of the burn and the skin round it are cleaned. It is the latter which is most likely to be septic, as it has not been properly burnt, so it must be cleaned with especial care. On this depends the entire success of the treatment with tannic acid, and I venture to say that *if your treatment fails it will be because the area has not been cleaned properly, and for no other reason whatsoever*. All dead skin must be removed, debris picked off, blisters pricked, the raised skin cut away, and the whole area washed with soap and warm water, using a flannel or sponge. When the area is thoroughly clean—particularly round the edges—it should be sponged with ether. The tannic acid dressing is then applied.

The Compress

Into the 2 per cent. tannic acid solution, made up as described, dip a dressing of three layers of sterile lint or six layers of sterile gauze, cut to extend three inches beyond the obvious edge of the burn. Take it out dripping, and apply loosely and evenly over the burnt area. Then bandage the dressing firmly into position and leave it to dry, with the area rendered immobile by skeleton splints or suitable fixation: this is perfectly simple, and keeps the patient warm. If the burnt area is large a cradle should be used, and extra heat must of course be applied to warm the patient; but do not let the heat be too strong or the compress will dry before the tannic acid has had time to penetrate and secondary shock will subsequently develop, as the deeper damaged tissues are not coagulated. An electric lamp a little way off, or a hot-water bottle held near the dressing, will be sufficient to dry the compress slowly, and, incidentally, will not concentrate the solution.

After-treatment

The patient must be kept warm and fluid be given freely to combat collapse. The dressing should be left untouched for two weeks approximately, by which time the coagulum will separate naturally when the bandage is cut. Fixation of the burnt area must be maintained for the first twenty-four hours at least, so that the coagulum of tannic acid can solidify, and if the burn is in any of the flexures of the body the limb must be extended by splints, so as to avoid contraction and subsequent deformity from destroyed subcutaneous tissue or muscle. A burn extending all over the hand, for instance, would entail separating the fingers with rolls of bandage between the knuckles, so that they would not become webbed at the base and leave the hand deformed. In first or second degree burns these splints may be removed in forty-eight hours in most cases, but with deeper burns they must be retained till the coagulum separates, and often have to be reapplied for some time after this.

At the end of two weeks cut the bandages and the coagulum will lift away from the burn. Any areas that are inclined to stick should be left a day or two longer, when they too will come away neatly.

Complications

Various complications may occur during the course of treatment.

1. *Cracking of the coagulum* results unless efficient fixation is maintained for the first twenty-four or forty-eight hours, and is an indication that the dressing must be removed and the burnt area re-tanned with the part properly fixed. Similarly, if hexyl-resorcinol or acriflavine solution is used a soft and unsatisfactory coagulum may result, and this is also an indication for re-tanning.

2. *Sepsis* may occur, though in this respect it must be realized that the escape of a little serous or sanious discharge round the edges of the coagulum is of frequent occurrence and does not mean that sepsis is present. Pain, pyrexia, and a discharge of frank pus alone indicate sepsis; these call for the removal of the loosened coagulum, thorough re-cleansing of the area, and reapplication of a tannic compress, when a satisfactory result will be obtained.

3. In burns which have destroyed the skin *ulceration* will of course be present when the tannic acid coagulum separates. All that is necessary in these cases is continued splintage to prevent contracture and the application of a suitable lotion, or the use of some method of skin grafting to effect healing, which can be obtained with very little scarring.

Special Burns

Burns in certain situations, such as the face, perineum, and buttocks, are better treated, if possible, by the spray, though with care an excellent result can be obtained by the compress. In the case of a burnt hand great care must be taken in the application of compress and bandages to individual fingers and the clefts between them, as well as in the splinting of the hand and fingers and the fixation of the latter apart by means of rolls of bandage stitched between the digits well clear of the clefts.

Up till now only fire and water burns and scalds have been considered, but there are also many very bad *chemical burns*. Tannic acid is equally good for these, but the chemical that has inflicted the burn must first be neutralized completely before the tannic acid is applied.

In any such burn washing freely with a large quantity of warm water is essential, and in addition an *acid burn* must be neutralized with an *alkali*—bicarbonate of soda, for instance—while an *alkali burn* should be neutralized with a 2 per cent. citric acid solution; this is best, as it penetrates the tissues, while most of the other acids (for example, acetic) act only on the surface.

Electrical burns are very difficult indeed to treat. They are often fatal, and so the need for treatment does not arise. Only a very small burn shows—a sort of stab in the flesh where the current has entered. The patient should be moved away from the current at once—even before it is switched off; but of course the rescuer must take the greatest care not to become electrocuted himself. The patient must be treated for collapse and the small burn with tannic acid, but very little else can be done. Pain will be intense through all the nerves. A certain amount of relief can be obtained from the use of veronal tablets, but morphine must on no account be given.

In the case of burns from *mustard gas* the medical man must protect himself by using rubber gloves and, of course, by wearing an overall and respirator. The first thing to do is to neutralize the gas with bleaching powder emulsion, then wash the area with plenty of water, dry over with ether, and put on a tannic acid compress.

For *lime or gas burns* in the eyes irrigate the eyes first with a neutral fluid such as a 2 per cent. solution of citric acid, and then instil sterile castor oil and a drop of 1 per cent. atropine solution.

Lastly I will just mention *sunburn*, which, after all, is a burn and often requires specific treatment. The popular idea of treating sunburn is to put on grease and lie out in the sunshine. Of course as a result the patient is very nicely basted, and suffers all the pain of a fire burn. Here is a prescription which has been found very beneficial when dealing extensively with sunburn at Territorial camps:

R. Calamine	400 grains
Zinc oxide	400 "
Tannic acid	100 "
Glycerin	1 ounce
Water	1 pint

This lotion should be applied at hourly intervals until the irritation is relieved. Incidentally the lotion has itself a pleasant tanning effect on the skin.

Other Methods of Burn Treatment

Many other methods have recently been used, but the majority fail in that they do not produce coagulation; considerable shock therefore ensues from the escape of fluid, and in severe burns this frequently has fatal results. Thus they cannot in the majority of cases be considered as efficient as a weak solution of tannic acid.

Crude cod-liver oil has had a considerable vogue, but is no better than any other grease dressing, though, as stated, it holds sepsis largely in check.

Gentian violet (1 per cent. aqueous solution) is an excellent antiseptic and keeps burns clean. No better treatment can be used for small first and second degree burns. It must be realized that absorption takes place in all burns, and the urine may be discoloured, while there is of course a violet discoloration of the skin, which persists for a considerable time. Moreover, as no coagulation of the damaged tissues occurs shock will result from loss of fluid. This antiseptic unfortunately does not combine well with tannic acid.

statement issued by him on November 9 he had said that boiling of the water was unnecessary, he said that the matter was discussed in the Public Health Committee, which so decided. He did not agree that it would have been a helpful precaution. The water supply was already being effectively chlorinated two days before there was anything to suggest that water was the cause of the outbreak. Asked if he refused to take any suggested precautionary measures on the ground that a panic would be created, he said that the word "panic" was used at a meeting of residents in the area which he had attended: if he used it himself it was in connexion with the broad-casting of information.

Notification to Croydon Practitioners

In reply to a further question, Dr. Holden said that the twenty-six doctors in the affected area of South Croydon were informed of an outbreak of typhoid on November 1, and all the 150 doctors in the borough on November 4. If a local medical committee had been available he would have been happy to consult it.

Is there a local Division of the British Medical Association?—Yes.

Could you not have applied to the officers of that Division?—If I had applied to the secretary of the Division, whom I know very well, he would have called his committee together, but that would have meant delay.

They are all on the telephone, surely a meeting could have been summoned the same night. You do not suggest that had that been done any one of those gentlemen would have refused to treat it as a matter of extreme urgency? Can you imagine the secretary refusing to give it immediate attention?—I think the secretary would have done what he thought was right. I have always found the secretary of the Division ready to co-operate.

Mr. Lyons referred to the letter in the *Times* of November 22, signed by Lord Dawson and Sir Kaye Le Fleming, and taking up their remark about lack of co-ordination between departments, asked what co-ordination there was between Dr. Holden's department and that of the borough engineer. Dr. Holden replied that the co-ordination was in the submission of the results of the bacteriological examinations to him for his opinion.

The Chairman (Mr. H. L. Murphy) said he would not suggest that this cross-examination was irrelevant, but it had arisen out of some temperate comments on the *Times* letter which were made by Sir Walter Monckton at the beginning of the proceedings. He understood that Sir Walter's remarks were addressed to the point that the two distinguished signatories, like many much less distinguished persons, did not appear to have made themselves acquainted with the terms of reference of the tribunal.

Sir Walter Monckton said that that was the case. He was making the assumption that Lord Dawson and Sir Kaye Le Fleming had not seen the terms of reference, which were not confined to an inquiry into the causes of the outbreak, but extended to the steps taken to deal with it. Had they done so they would have refrained from stating that there was a defect in medical administration in Croydon.

Preventive Inoculation

Mr. Lyons asked Dr. Holden what were his grounds for stating that he had consulted several medical colleagues on the subject of prophylactic inoculation, and medical opinion was against it. Dr. Holden replied that he had consulted the borough bacteriologist, also Dr. E. T. Conybeare of the Ministry of Health, and a local practitioner, and their opinion was against inoculation on the ground that immediately afterwards—he thought it was a well-known fact pertaining to all methods of inoculation—a negative phase occurred during which the individual might be more susceptible. He was definitely advised not to recommend universal inoculation.

On the general question of co-operating with the local profession, Dr. Holden said that he had been medical officer of health for a good many years, and he had never wilfully ignored private practitioners. In this typhoid outbreak he had followed the practice always adopted by medical officers of health.

He added that he had attended a meeting summoned by the B.M.A. Division later in the month (the 24th), when a number of recommendations were made. In reply to the Chairman (Mr. Murphy) he said that he was himself a member of the B.M.A. and of the Croydon Division, but he could not attend the meetings regularly as the time conflicted with meetings of his official committees.

Co-operation with the Local Profession

Dr. Holden was next cross-examined by Mr. A. H. Forbes, appearing for the Croydon Division of the B.M.A. and the Local Medical and Panel Committee. He directed attention to an article in the *Medical Officer* of November 27, which stated that it was neither usual nor useful for the medical officer of health in times of urgency to confer with representatives of the local medical profession. He hoped Dr. Holden did not agree with that "heresy." Dr. Holden repeated that if there had been a local committee of doctors available he would have been happy to seek their help, the Public Health Committee consenting.

The article further says, "Lord Dawson is not fully acquainted with modern public health practice." Do you approve any modern public health practice which considers it generally not useful for the medical officer in times of urgency to confer with local medical practitioners?—I think that if the local profession have a standing committee it could and would be of great assistance to the medical officer of health.

Then if the local medical practitioners had had in existence at the time of this outbreak a standing committee you would gladly have co-operated with it?—Provided that the standing committee was recognized by my council.

And you would have furnished the committee with all relevant information?—Subject to the consent of my committee.

Typhoid in its early stages is difficult to diagnose?—From clinical symptoms alone, yes.

And it is important that diagnosis should be made as early as possible, both from the point of view of the patient's nursing and diet and from the point of view of contacts?—Yes, but I do not think that in the early stages of typhoid there is much risk, if any, from contacts.

Is there risk at any stage prior to the probable date of diagnosis?—That is a difficult question; the date of diagnosis may be as late as the third or fourth week, and in that case there might be a certain risk.

But in practice, as soon as typhoid was diagnosed, one would advise all the usual precautions to prevent infection by contacts?—Yes, understanding by "contacts" those attending the patient.

It is ordinary practice as soon as even a tentative diagnosis is made to give instructions in the household concerning precautions?—If I was the medical attendant I should give such instructions.

Have you ever been in private practice?—A long time ago, for about six months.

When you notified the doctors of South Croydon on November 1 how did you discover their names?—From a list of doctors in my possession and from a local street directory.

I want to draw attention to the letter you sent. It tells the doctors nothing as to the possible cause of the outbreak nor does it say where the cases are occurring. Is that likely to be of any use to men in private practice?—Yes.

Even though the letter says nothing to indicate that the source of infection was water?—Yes.

Do you agree that if at any time you could have told these doctors that the source of infection was water and that the water was supplying the houses in certain streets it would have been of immense value to them in making a diagnosis or a provisional diagnosis?—I do not see that it would have been any more useful than drawing their attention to the fact that typhoid was in Croydon, more especially, at a time when I was not sure by any means that any particular item of food or drink was implicated.

I suggest that if a practitioner sees a doubtful case and knows it is within an infected area, the house being on an infected water supply, he would diagnose the case as typhoid at once?—When he knows that the water supply is infected, yes. But I did not feel justified in notifying the practitioners concerning any particular source of supply until I had more information at my disposal.

Did that apply as late as November 6?—Strictly speaking, it applies even now, for it is all presumption.

Mr. Forbes had not completed his questions when the court rose.

Silver Nitrate.—A 10 to 20 per cent. solution of silver nitrate rubbed into the burnt area produces a tough and rapid coagulum; but here again it does not always penetrate into the deeper tissues, and so a certain amount of collapse occurs in severe burns. Next to tannic acid, however, an application of silver nitrate and gentian violet gives the best results; but here once more the primary essential cleansing of the burn and surrounding area is necessary if sepsis is to be prevented. The patient having been given a dose of sedative, and the area of the burn being cleansed as already described under the tannic acid treatment, the whole of the burn area is painted or sprayed once with a 1 per cent. aqueous solution of gentian violet and is thoroughly swabbed over with a 10 to 15 per cent. solution of silver nitrate, care being taken that the silver nitrate does not escape over the surrounding skin. The area is now again sprayed or painted with a 10 per cent. solution of gentian violet at fifteen-minute intervals for five or six times, the patient in the meantime being kept warm under an electric cradle and given plenty of fluids to drink. Should it be necessary the painting or spraying with gentian violet can be repeated once or twice daily for the next day or two. From the use of this method the American authorities report a mortality of 7.3 per cent., apparently for both burns and scalds; this is considerably higher than that from weak tannic acid solution, as might be expected when one realizes that in the case of extensive burns the silver nitrate coagulum does not extend into the deeper damaged tissues.

Many other antiseptics have been combined with tannic acid instead of perchloride, the most popular of which is acriflavine. This substance, however, in my experience, is not satisfactory for the reasons already given. The same objections apply to the great majority of antiseptics that have been tried in this connexion.

Finally, I would say to those practitioners who bring forward instances where some particular treatment has given good results in individual cases of burns that any treatment may be successful in the case of a slight burn, but that in severe burns cleansing and coagulation alone can be relied on to preserve the patient's life, with the minimum of disfigurement and the maximum relief of pain and the prevention of collapse and sepsis.

CROYDON TYPHOID INQUIRY EVIDENCE OF EXPERT WITNESSES

The tribunal inquiring into the outbreak of typhoid fever in Croydon continued its sittings over Christmas. The first evidence called on behalf of the Corporation was that of a geological expert, who spoke as to the structure of a gathering ground of the suspected well, and a consulting water engineer, who testified as to the character of the water from the Addington supply. The latter witness, Mr. S. R. Rafferty, agreed that this well had been known for a number of years to show variations in the quality of the water. He agreed also as to the danger from workmen's latrines in the vicinity during such time as some work was proceeding on a school belonging to the local authority, and as to the undesirability of the presence of a pig farm at this particular spot, though he would not say that this was a possible source of danger. It was further put to this witness that on the other side of the wood from the reservoir there was a ground, just outside the Croydon boundary, which was used as a week-end camping place for some hundreds of people and had no sanitary conveniences of any kind. The witness replied that there had been no means of dealing with such a state of affairs, unless it could be held to constitute a local nuisance, until the passing of the recent Public Health Act.

Medical Officer of Health's Evidence

Dr. O. M. Holden, medical officer of health for Croydon, who was in the witness chair for three days, traced the history of the epidemic and of the inquiries set on foot regarding water, drains, etc., immediately the cases occurred. He had been under the impression that the whole of the Croydon water was chlorinated, and was surprised to hear that the high-level supply, which included that from the Addington reservoir, was not. Chlorination of the Addington well began on November 1. He had studied reports of a predecessor of his in 1905-8 regarding the liability of the Addington well to surface pollution. He knew the conditions on the gathering ground, and for some time he had been a little uneasy about this well; he had drawn attention to the fact that the analyses of the water from this well did not appear to be satisfactory and had recommended chlorination.

In reply to his own counsel, Mr. Sandilands, K.C., Dr. Holden said that the duties of the medical officer had been considerably increased during the last twenty years, but the water supply had never been put upon him. He did not wish to deny that as medical officer he had a certain responsibility. He considered the limit of his responsibility to be to advise the responsible authority on the bacteriological analyses, which were the only material he had before him. At the end of 1930 he advised that chlorination should be considered by the borough engineer, and he had been under the impression that chlorination was carried out at Addington well from that time. It was put to him by Mr. Lyons, counsel for the South Croydon Typhoid Outbreak Committee, that in 1931 he had reported that some solid contamination had been getting into the Addington water, and that if it were built on to any greater extent and cesspools multiplied there would be grave danger to the public health, and that when in 1936 he reported that the water supply was satisfactory he omitted to point out what he really knew—namely, the danger which he had appreciated five years earlier. Dr. Holden denied this.

He was also asked what steps he took to prevent householders drinking water from their own cisterns after he knew the water to be contaminated. Dr. Holden replied that the precautionary measures taken on November 1 at the source of supply safeguarded the water by November 3, on which date he first knew the water to be infected, but he agreed that nobody visited the unoccupied houses, drained off the water, and chemically treated the tanks.

Precautionary Measures Adopted

When the inquiry was resumed on Tuesday, December 28, Dr. Holden was further cross-examined by Mr. Montagu Lyons, who asked first as to the dates when the Addington well was chlorinated. The witness said that the records would be with the borough engineer. The borough engineer, like himself, had been under the impression that the supply had been continuously chlorinated since an earlier complaint was made, but he discovered at the beginning of the outbreak that only intermittent chlorination had taken place.

Asked how many cases would be brought to his notice in the same area before he decided that an outbreak was probably beginning, he replied that two or three cases of any infectious disease in the same neighbourhood would cause him to think seriously of the likelihood of spread. But he desired to make it plain that at first the water was not specially considered. It was one of a number of things, including milk and other articles of food, which had to be examined, and there was no reason at the end of October, when the first four or five cases had been notified, for giving water the priority.

Dr. Holden was questioned as to a statement he had made that in recent years water had seldom been found to be the cause of typhoid. He said that the statement was a fair one, though it might have been amplified. Certainly the most serious outbreak of recent years (Bournemouth) was not due to water. Asked why in a

Part of Plymouth Hoe, showing the bathing pool and terraces, with Drake's Island in the middle distance and Mount Edgumbe in the background.

now dwelling within the propound boundaries." To commemorate his election His Worship provided a feast, composed of a pie of "all sorts, of fish, flesh, and fowl that could be gotten. It was fourteen feet long and four feet broad, and an oven was built for the purpose of its baking." And to this day Mayors on election day give their luncheons, though on more modern lines.

Drake as Mayor

Sir Francis Drake was Mayor in 1581. Although better known for his exploits at sea—and whenever Plymouth is mentioned Drake finishing his game of bowls before attacking the Armada comes to mind—it should be remembered that it was he who first provided the town with an adequate water supply. Also regarded as of sufficient importance to be placed on record is the fact that he "set a mariner's

The City Guildhall.

compass on the Hoe." More notorious, though less practical, was the action of another Mayor who struck the town clerk—as he sat upon the bench, because the official addressed him without his title of "Worship."

Invaded by the French, "spoiled by the Bretons," Plymouth through the centuries suffered from piracy, and in addition to the plague was a victim of a "sweating sickness" known as *sudor anglicus*, which raged in the fifteenth century. But the famous Sabbath Day siege, well known to students of the Civil War, marked an epoch of first importance in national as well as local history; and since then, generation after generation, its name has been writ large in the annals of the country, until to-day it ranks as a great naval arsenal, as an important military garrison and seaplane base, and as a commercial port visited by steamers to and from all parts of the globe.

ONE HUNDRED AND SIXTH ANNUAL MEETING
OF THE
BRITISH MEDICAL ASSOCIATION
PLYMOUTH, 1938

THE one hundred and sixth Annual Meeting of the British Medical Association will be held in Plymouth next summer under the presidency of Dr. Colin D. Lindsay, senior physician to the Prince of Wales's Hospital, Plymouth. The Sectional Meetings for scientific and clinical work will be held on Wednesday, Thursday, and Friday, July 20, 21, and 22, the morning sessions being given up to discussions and the reading of papers. The Annual Representative Meeting for the transaction of medico-political business will begin on the previous Friday, July 15. The full list of presidents, vice-presidents, and honorary secretaries of the seventeen Scientific Sections will be published in an early issue of the *Supplement*. Other details of the arrangements for the Annual Meeting will appear in subsequent issues. We publish below the first of a series of descriptive and historical articles on Plymouth and its medical institutions.

PLYMOUTH YESTERDAY AND TODAY

In choosing Plymouth as the venue of their Annual Meeting this year the British Medical Association will come to "no mean city." Its claims to distinction are many. It has played a prominent part in history and the development of the Empire, and to the sciences and arts its sons have made no less a contribution.

As in most nations, but seldom in towns, the history of Plymouth begins in the region of myth and legend. Her geographical position and natural surroundings were such as to appeal to those people who inhabited ancient Britain, and it is claimed that the Damnonii not only lived there but spread over the county to adjacent Cornwall. During the Anglo-Saxon period Plymouth, first frequented as a fishing station, gradually rose into a place

of note. Late in the eighth century the Danes landed in England, and not many years afterwards made their way into Devonshire, which they are reputed to have inhabited for some time subsequent to 786. Devon was one of the last districts to submit to Norman rule. In Domesday Book, compiled in 1086, Plymouth, then known as Sutone (South Town), is described as being held by the King in demesne. Afterwards the town was divided and the greater part went to the Priory of Plympton, with which rested its government for many years.

First Charter

As far back as 1439 the charter of incorporation was granted, and the first Mayor, William Ketriche, was described as "one of the most honest and discreet men

Burrator, the source of Plymouth's water supply.

HEALTH OF THE SCHOOL CHILD

CHIEF MEDICAL OFFICER'S REPORT*

Sir Arthur MacNalty, in his annual report as Chief Medical Officer of the Board of Education for 1936, points out that education includes physical education, and that in order to obtain full advantage from it a child must receive an adequate and balanced diet. To achieve this end it is important that meals provided for school children requiring supplementary nourishment should be rich in those essential foodstuffs which may be deficient or lacking in their home dietary. Such articles are milk, cheese, eggs, butter, green vegetables, fruit, and meat. The question of the proper selection of children for free meals is dealt with, and three essentials for success are laid down—accurate ascertainment, efficient provision, and a proper income scale. The need for greater appreciation of the value of milk and for improvement in the arrangements and dietaries in the schemes for provision of solid meals is emphasized. In this connexion the example of certain authorities who have made substantial improvements in their schemes is quoted. Mention is made of the importance of teaching girls the art of managing a home efficiently, for experience shows that malnutrition in the child is sometimes the result of bad home management rather than of poverty.

The introduction concludes with a passage relating to school camps, in which the following sentence occurs:

"If the world could be remoulded to our liking every school would be an open-air school in a country or seaside setting, with ample facilities for playing fields and the seashore of nature."

Nutrition of the School Child

In Chapter I an account is given of the additional information on the subject of nutrition which became available during the year. Several important reports have appeared, notably a memorandum on the *Nutritive Value of Milk*, prepared by the Advisory Committee on Nutrition; the first report of the same committee; and the report of the Technical Commission on the *Physiological Bases of Nutrition*.

From the reports of school medical officers it would appear that in many areas the physique of elementary school children as shown by height and weight measurements has continued to improve. The method of clinical assessment introduced in Administrative Memorandum 124 is again discussed and a comparison made between the findings for 1935 and 1936. During 1936 the nutrition of 1,726,755 children examined at routine medical inspection was assessed by some 1,300 observers. The percentages placed in the four categories were almost identical with those in 1935: 14.6 per cent. in A (excellent), unchanged; 74.2 per cent. in B (normal), as against 74.1 per cent. in 1935; 10.5 per cent. in C (slightly subnormal), as against 10.6 per cent. in 1935; 0.7 per cent. in D (bad), unchanged.

The nutritional condition of children in the Special Areas is discussed, and the need for increased provision of extra nourishment in these areas is stressed. Other subjects discussed in this chapter are the causes of sub-normal nutrition and physique, figures for heights and weights in different areas compared with those of the same areas in previous years, a comparison between the nutritional state of a group of secondary school children in Surrey and another group in Spennymoor.

Provision of Free Meals and Milk

During the year 139,662 children received free solid meals. The total number of meals, including milk meals, provided free of charge increased from 87,000,000 in 1935-6 to over 100,000,000 in 1936-7. This increase of 13,000,000 was due to the rapid rise in the number of

free milk meals provided, which has increased from 42,200,000 in 1934-5 to 63,700,000 in 1935-6 and 78,300,000 in 1936-7. The statistics are followed by a discussion of the Milk in Schools Scheme, in which certain difficulties in the operation of the scheme are mentioned and in which a table is given showing the advantage of fresh milk over certain dried milk preparations. Examples are given of the dangers which arise from raw milk, and these show that the Board's policy of advising that pasteurized milk should be used wherever possible is fully justified.

Physical Education

In January, 1936, the Board issued Circular 1445, which was a statement of its views as to the policy to be pursued in regard to two aspects of physical education and was designed to assist authorities and others in preparing a comprehensive plan of development. The later part of the year saw the initiation of further Government plans for encouraging recreational and physical activities among those who have left school.

Reference is made to the setting up of the National Advisory Council for Physical Training and Recreation, and the chapter also contains a description of the duties of organizers of physical training.

Medical Inspection

The discussion of the system of routine medical inspection which was begun in the 1935 report is continued. The prevalent opinion of school medical officers appears to be that changes which may be introduced should take the form rather of additions grafted on to the present framework of the system than of radical changes in the framework itself. The statistics given in the chapter include those relating to the staff of the School Medical Service and to the findings of medical inspection. The subjects of medical inspection and treatment in secondary schools and of inspection and treatment in junior instruction centres for the unemployed are also discussed.

Medical Treatment

The relations between the School Medical Service and other bodies such as the voluntary hospitals, public health authorities, and the medical profession generally are discussed, and the need is emphasized for full co-operation between all those who take part in the medical treatment of school children. Schemes for the treatment of certain defects are discussed, and it is pointed out that orthopaedic schemes are a good example of what can be achieved by the co-operation of numerous bodies, both public and private.

Other subjects considered in Sir Arthur MacNalty's report are nursery schools and the care of young children; the School Dental Service and the Medical Research Council report on the influence of diet on caries in children's teeth; the teaching of mothercraft and hygiene in schools; and the education and training of blind children. During the year a medical officer of the Board, in company with H.M. Inspectors, paid visits to a number of school camps for elementary school children. A general description of these camps is given and recommendations are made with regard to them, the importance of ample floor space and ventilation in the sleeping-quarters being emphasized. Lastly, attention is drawn to the importance of continuity of medical care throughout life and to new legislation connected with the National Health Insurance Scheme and with the Factory Acts designed to that end.

Dr. Carl Koller (Karl Köller), who in 1884 at the age of 27 introduced cocaine as a local anaesthetic in ophthalmic surgery, celebrated his eightieth birthday in New York on December 3.

* *The Health of the School Child*. Annual Report of the Chief Medical Officer of the Board of Education for 1936. London: H.M. Stationery Office. (2s. 2d., post free.)

Noted Medical Men

Physicians and medical men of Plymouth were among its earliest scientific observers, and several outstanding personalities come to mind. Dr. James Yonge, F.R.S., who died in 1721, not only practised with much success but wrote a number of philosophical and medical works. Dr. Huxham, the author of a celebrated treatise on fevers which was translated into several foreign languages, practised and died in Plymouth. It is said that the adoption of the principles enunciated by him saved the life of the then Queen of Portugal.

Dr. John Mudge gained high reputation, not only by his skill as a medical man but by his knowledge of mathematics and optics. He wrote several medical works. So also did Dr. Woolcombe. Dr. Edward Moore dealt largely with zoological subjects, and Mr. C. N. Moore was the author of several works on cancer. Sir William Snow Morris, the scientist, was born at Plymouth, and John Prideaux became eminent as a chemist. Dr. Leatherby, medical officer of health of the City of London, who died in 1876, was a Plymouth man.

Jonathan Heard was an expert on matters electrical and chemical. A public lecturer at the age of 17, he lost his sight four years later through a sudden explosion of silver fulminate, but despite this handicap continued his work, particularly as a public experimenter.

In more recent days one recalls the names of Dr. Cloy, Dr. Paul Swain, Dr. Hingston, a well-known local philanthropist, Dr. Rolston, and A. Bertram Soltau, who had the rare distinction of holding the Fellowship of both the College of Physicians and the College of Surgeons, as a few among many who carried on a noble tradition which is being worthily maintained to-day.

An Up-to-date City

It must not be assumed that Plymouth, which was raised to the dignity of a city in 1928, is content to live on its past. It may have first elected its Members of Parliament as far back as 1292, and its recordship may date from 1480, but in every essential respect it is modern, with broad thoroughfares, imposing public buildings, and all the amenities that reasonable enterprise demands. As "the centre of a hundred tours" it can meet the most exacting claims of the visitor, who will undoubtedly be impressed by its contrasts.

It is possible to play bowls under the watchful eye of Drake, to stroll on the Hoe—the finest promenade in Europe, some say in the world—and watch with increasing fascination the ever-changing panorama of the Sound, fanned on one side by the wooded slopes of Mount Edgcumbe, and on the other by the heights of Bovisand. The rocky foreshore, with its unique buildings, provides an ideal spot for bathing, and on the terraces immediately above sun-bathing can be indulged in.

Elizabethan Plymouth

Near by is the Smeaton Tower, which for a century stood on the Eddystone Rocks until replaced by Douglass's lighthouse in 1882. A walk of a few minutes brings one to the Elizabethan Plymouth, passing en route the Citadel with its massive ramparts built by Charles II. No. 32, New Street is a typical Elizabethan house recently restored, and it is possible here to glean some idea of the home surroundings of the old sea-dogs of Devon. On one of the entrance piers to Sutton Pool stands the *Mayflower* Memorial, marking the spot where the Pilgrim Fathers embarked for America. The rebuilt residence of Cookworthy, whose name is linked with Plymouth china, and a distillery, formerly a religious house of the Black Friars, are in the vicinity.

Ancient and Modern

The mother church of St. Andrew dates from 1385. It has a fine tower built by Thomas Yogge, a wealthy merchant, in the time of Henry VI, the town "finding the stuff." St. Andrews, which was restored in 1874-5 by Sir Gilbert Scott, stands on the eastern side of a spacious square. On the southern side is the Guildhall (Early Pointed), some sixty years old, opened by Edward VII when Prince of Wales. Its beautiful painted windows portray five or six hundred years of Plymouth history. On the northern side are the municipal buildings, and in the Mayor's Parlour is to be seen the White Rod of the Lord High Steward, an office long held by one of the Royal Family.

Devonport and the Navy

Although Devonport and the former township of Stonehouse between were once separate entities, they are now incorporated into the municipality of Plymouth. But Devonport, with its extensive dockyards, its naval barracks, and its Royal Naval Engineering College, possesses an individuality all its own. It has a big part to play in national defence, and in the immense naval docks are all kinds of ships of war in various stages of completion. Naval uniforms are to be seen everywhere, and thousands of workmen pour through the gates daily to and from their work. The main establishment is the North Keyham Yard, where extensions were completed in 1907 at a cost of nearly £5,000,000. Further improvements are now under consideration. The Royal William Victualling Yard, at the gate of which is a statue of William IV, and the headquarters of the Royal Marines, are in Stonehouse.

Mention should be made of the city's museum and art gallery with its many treasures—one among the places to be visited. Another building which should be visited is Plymouth Institution, where the pursuit of the arts and sciences continues with ever-increasing vigour. Its museum, and an extremely valuable reference library containing some priceless works, are well worth inspection. It is interesting to note that in a long line of distinguished men the name of Dr. J. Elliot Square, member of an honoured family in Plymouth, appears as a President.

It may be judged that the visitor to Plymouth will not need to seek that which interests and stimulates the imagination. With almost a plethora of these things the problem will be what to miss because of other demands on time.

The eleventh annual report of ULAWS (the University of London Animal Welfare Society), 42, Torrington Square, W.C.1, has now been published. Sir Frederick Holday, president of the society, draws attention in a foreword to the support which animal welfare is receiving from scientific men and women. The work of ULAWS during the past year has expanded considerably. In the branches in ten colleges of the University of London a large number of meetings on humanitarian and natural history subjects were held. In addition, members, both graduates and students, delivered lantern and film lectures in schools, clubs, women's institutes, etc. There have been important developments in the society's campaign against the gin trap. During the year the House of Lords Select Committee on Agriculture (Damage by Rabbits) issued its report. ULAWS welcomes the positive recommendations made in this report, but points out that on questions of fact the Select Committee has achieved a compromise between conflicting opinions and interests rather than scientific appraisal of the evidence. It claims that the progress made towards solution of the problem of trapping is "a justification of the scientific approach to problems of animal welfare."

the common signs of leprosy in India was visible enlargement of the auricular nerve; this was not his experience in cases in Nigeria. Dr. CHESTERMAN supported Dr. Howard's statement regarding the rarity of thickened nerves in African lepers.

Sir JOHN MEGAW said that in India leprosy was often a mild disease. He deprecated over-exercise or exercise in the heat of the day in leper establishments, emphasized the importance of a nourishing diet, and expressed surprise that specific treatment with leprosy antigen prepared from the lesions in nodular leprosy had not been given a more extensive trial. Dr. A. FELIX drew attention to the recent experimental transmission of leprosy to the Syrian hamster, and suggested that the leprosy tissues of this animal might prove a satisfactory source of antigen supply. Dr. C. J. AUSTIN had on two occasions operated on lepers in Fiji with nerve abscess in cutaneous leprosy; he wondered if the tuberculoid cases really constituted a type distinct from the nervous or cutaneous types. Dr. GUSTAVE TAYLOR of Formosa said that among Chinese lepers demonstrable enlargement of nerves was common. If the patient turned his neck so as to stretch the sternomastoid muscle the great auricular nerve was frequently palpable: not only could one feel it but one could actually see it.

In reply, Dr. W. HUGHES agreed that tuberculoid leprosy was very like sarcoid. He had not encountered nerve abscess in Malaya, but there 80 per cent. of cases were of the cutaneous type. Leprosy manifested itself clinically as nodular skin and trophic lesions; without cellular reaction there were no manifestations of disease, though bacilli might persist in the tissues. Dr. E. MUIR said he had seen three or four cases of nerve abscess in cutaneous leprosy; he thought two of the patients had developed caseous lesions within the nerves as a result of deterioration of health. Nerve leprosy was common in Southern Nigeria and India. He could not say why it was not found more often in Malaya. Demonstrable nerve enlargement was common; he had been studying leprosy for some years before he realized how really common it was.

BRONCHOGENIC CARCINOMA

At a meeting of the Liverpool Medical Institution on December 2, with the president, Professor R. E. KELLY, in the chair, a discussion was held on bronchogenic carcinoma.

Dr. C. S. ANDERSON said that there had been a small real increase in the incidence of bronchogenic carcinoma in recent years. The great majority of, if not all, lung cancers originated in bronchi; they might be divided macroscopically into four types—hilar, nodular, miliary, and diffuse. Microscopically they might be squamous, adenocarcinomatous, or anaplastic, and the extreme pleomorphism of the cells made definite classification very difficult. Diagnosis was established by the clinical pathologist from a study of the sputum or of sections removed at biopsy.

Clinical Pathology

Dr. ROBERT COOPE discussed the pathological basis of the signs and symptoms. An early neoplasm appearing in a bronchus acted as a foreign body and produced a cough which was short, hard, perhaps hacking, and at first quite unproductive. As the nodule increased in size it might ulcerate and bleed, giving rise to haemoptysis. When the growth was large enough to produce an appreciable, but still partial, blocking of a large bronchus, it seriously interfered with the proper ventilation of the lung. A localized and unilateral wheeze might be heard, and dyspnoea might appear early. The poorly aerated part of the lung was very susceptible to infection. With complete blocking of the bronchus the lung beyond it became deflated and collapsed (obstructive atelectasis).

Obviously quite a small growth might completely block even one of the larger bronchi at a time when there were few symptoms and the patient appeared comparatively well; the resulting physical signs were a lack of expansion of the lung, dullness to percussion over the affected lobe, and a wide area of silence. In other words, the physical signs might be out of all proportion to the symptoms—in striking contrast to the state of affairs in simple abscess or tuberculosis of the lung. Suppurative changes in the distal part of the lung were likely to occur in the form of atelectatic bronchiectasis, lung abscess, pleurisy with or without effusion, empyema, or pyopneumothorax. The combination of infection with defective lung aeration sometimes resulted in a surprisingly early appearance of clubbing of the fingers.

Long before it had completely obstructed a bronchus, however, a malignant bronchial growth might have invaded local structures, and if it happened to be near the hilum of the lung would then show some of the invasive manifestations of a mediastinal tumour. Paralysis of the phrenic nerve with consequent elevation of the diaphragm was particularly important; it was especially apt to occur on the right side by secondary involvement of the small mass of glands through which the nerve passed. If the neoplasm began in a smaller bronchus near the periphery of the lung there would be early pleural involvement, and perhaps effusion; extension also occurred towards the hilum, with invasion of the corresponding lymph glands. One type of the disease was caused by a growth which did not obstruct a bronchus until some considerable time after it had spread, fanwise, along the lymphatics, producing a chronic indurative condition, with the x-ray appearances of "unresolved pneumonia"; the same x-ray picture might be given in the early stages of infection of the lung distal to a bronchial stenosis. The "pneumonia" did not resolve, however—a sinister persistence in a person at or beyond middle age. At any time the growth might begin to necrose, producing an irregular fever, clubbing of the fingers, and toxæmia; in this event cavitation of the lung was much more ragged than that due to suppurative changes distal to a blocked bronchus. Secondary metastases might occur anywhere, and at times a metastatic growth in an obvious place, such as skin or skull, was the presenting sign; a secondary deposit without an obvious primary should always suggest carcinoma of the lungs. Finally, there were the general symptoms produced by any cancer; loss of weight and cachexia were usually late symptoms.

Early Symptoms

Persistent cough, haemoptysis, and dyspnoea were the most likely early symptoms; an analysis of the earliest symptoms of a series of fifty-four cases supported this, and underlined also the importance of secondary inflammatory lung lesions distal to the affected bronchus. In these cases there was an average duration of nearly six months between the earliest symptom and the time when the patient first came to hospital. In patients of cancer age haemoptysis occurring for the first time should be regarded as due to bronchogenic carcinoma until it was proved to be caused by something else. Similarly, in patients of that age who had not previously had "chest trouble," any cough, or "influenza," or atypical pneumonia, or pleurisy which did not clear up satisfactorily might be due to bronchogenic carcinoma. In an elderly person pleurisy with effusion, empyema, or lung abscess which appeared to have no obvious cause might be a complication of the disease. A cough accompanied by dyspnoea which was not adequately explained by the physical signs in the lung or by the condition of the heart, and which was of recent appearance, might be due to partial blocking of a large bronchus by new growth. All these conditions called for investigation. The pathology of the disease did not encourage much hope of cure. The growths which were likely to be diagnosed early were those which could be seen through the bronchoscope, and

Reports of Societies

LEPROSY

At a meeting of the Royal Society of Tropical Medicine and Hygiene, at Manson House on December 9, 1937, with the president, Lieut.-Colonel S. P. JAMES, in the chair, papers were read by Dr. E. MUIR and Dr. WILLIAM HUGHES.

Epidemiology and Control of Leprosy

Dr. Muir dealt with this aspect of the leprosy problem, pointing out that leprosy belonged to a certain stage of human development. It was rare among nomadic tribes and aborigines leading an unmixed tribal life, but tended to spread when primitive people settled down to agriculture, and when they first came into contact with civilization. Leprosy again tended to disappear when a certain standard of living and sanitation had been reached. Leprosy was a disease of the crowded house, room, and bed, and the more crowded and insanitary these were the more likely it was to spread. In India the joint family system had an important bearing. The rise and fall of the leprosy curve in an area was not due to the development of physiological immunity so much as to the growth of a mental and social immunity. As the disease increased in the community its members learnt to recognize it and take precautions. These precautions might not be adequate or sufficient to eliminate the disease, but they generally curtailed it. The place of treatment in the control of leprosy was an important one, but one which had often been exaggerated and misunderstood. We had no specific treatment for leprosy any more than we had for tuberculosis. The most we could say was that when leprosy was compared stage by stage with tuberculosis it proved somewhat more amenable to treatment than the latter disease. In both, the main reliance must be placed upon general methods and improvement of the health of the patient. When this could be secured—and with the help of certain special remedies, such as chaulmoogra oil and its preparations—the majority of cases might be expected to recover, though the more the disease advanced beyond a certain stage the more difficult and hopeless did it become.

One of the essential factors in the control of leprosy was the large, well-staffed leper settlement. In the modern leper settlement, some of the best of which might be seen in Nigeria, the patients were suitably housed and spent cheerful and useful lives. The well-run leper settlement was in fact a model village, or cluster of villages—a centre of culture and progress—not only benefiting its own inhabitants but potentially a source of enlightenment and sanitary and social development for the whole area. Leprosy in countries in which it was endemic was so inextricably bound up with economic, social, educational, and sanitary problems that its control could only advance simultaneously with the solution of these problems. It was significant that in this country the lazaret was the precursor of the modern hospital, and that many of our early public health laws were passed for the control of leprosy.

Tuberculoïd Leprosy

Dr. Hughes confined his observations to tuberculoïd leprosy, and in his introductory remarks pointed out that though the existence of giant cells of the Langhans type in leprosy had been vigorously denied by Hansen and Looft, Jadassohn had described them in 1898. Since then many workers had noted their existence. Wade was the first to give a systematic account of a special form of leprosy associated with a giant-celled or epithelioid infiltration. This form was much more closely allied to the neural than the cutaneous type, although, clinically, it

could be easily mistaken for the latter. The tuberculoïd lesion seemed to be common in races which had been afflicted with leprosy from time immemorial. It might in a way be regarded as an expression of racial immunity, or indeed of racial allergy, if such a term was permissible. According to the recent literature the incidence among Northern Indians was about 60 per cent. of the total cases of leprosy. Bacilli were very scarce in these lesions, and might be impossible to find except in serial sections. The tuberculoïd lesion in this respect resembled such conditions as, for example, lupus, Boeck's sarcoid, the syphilides, etc. Like other forms of leprosy it was subject to occasional exacerbations or "acute reaction." This was a local phenomenon not attended by fever, loss of weight, increased sedimentation rate, etc., which characterized acute reactions in the cutaneous type of leprosy.

In assessing the significance of tuberculoïd leprosy a comparison with the tissue responses in tuberculosis was inevitable. Both diseases were associated with an acid-fast bacillus and the epithelioid giant-celled lesion was common to both. In leprosy, however, there were two other types of tissue response—the chronic inflammatory type of exudate associated with early neural leprosy and the cutaneous exudate characterized by the lepra (Virchow, or foam) cell. The numerical relation between the bacilli and the cellular exudate in tuberculoïd leprosy presented a sharp contrast with that seen in the cutaneous type, and if a cutaneous case of leprosy responded to the same degree as a tuberculoïd case, the resulting tuberculoma would fill St. Paul's. Recession of the lesions during severe debilitating disease had previously been noted. If a tuberculoïd lesion receded the bacilli were so scarce at any time that such recession could be, and often had been, mistaken for cure. It was only to be expected that in countries where there was a high incidence of tuberculoïd leprosy superficial observations might easily lead to mistakes. In all probability this was the basis of many of the spurious "cures" in the literature of leprosy. It was quite common for authors to record "pushing" the heavy metals until the symptoms of metallic poisoning supervened. At this stage it seemed the highest percentages of cures—in reality recession of lesions—occurred.

Whatever might be the argument for abolishing the hyperergic state in the case of tuberculosis, as advocated by Rich, Pagel, and others, it was extremely doubtful if such measures should be resorted to in tuberculoïd leprosy. In this disease the prognosis was on the whole fairly good. Occasionally—for example, in cases of iritis—it might be justifiable to use drugs in dangerous doses to abolish the cellular exudate in the uveal tract. But the difficulty was to find a drug which would do this consistently. At the moment it was doubtful if any single drug or combination of remedies could be relied on to stave off the blindness which was such a distressing feature of these cases. The study of tuberculoïd leprosy was new, but already sufficient facts had been accumulated to give a fresh point of view in leprosy, and perhaps in other forms of proliferative disease.

General Discussion

In the discussion which followed Dr. J. M. H. MacLeod said that tuberculoïd leprosy was very like sarcoid. For many years histologists had been debating the relationship between sarcoid and true tuberculosis cutis in the same way as they were wondering what was the precise histological relationship between tuberculoïd and cutaneous leprosy. The bacillary position was of course different, because in nerve leprosy one occasionally found bacilli, but not often, whereas in sarcoid he had never succeeded in finding tubercle bacilli, though some other people had reported doing so. Dr. HOWARD pointed out that in Southern Nigeria the tendency was to develop a cutaneous type of leprosy, whereas in the north the neural and tuberculoïd types were found. Dr. Muir had said one of

Dr. JAMES FENTON from the chair pointed out that the medical officer of health worked under three Departments of State—the Ministry of Health, the Board of Education (which two were indivisible, the Chief Medical Officer of both Departments being the same individual), and the Home Office. He dissented from Dr. Stewart's remark about the medical officer of health and housing, and pointed to the great housing activity all over the country in the direction of which the medical officer had taken a fundamental part. In the subsequent discussion Dr. J. C. BRIDGE, senior medical inspector of factories, said that during his own term in the Factory Department the industrial medical service had become a new service altogether, and the larger it grew the better pleased would be those who had to administer the Factories Act. Personally he could not see how industry as such could produce tuberculosis to anything like the extent that bad housing conditions could produce it; nevertheless, there was a tendency to blame industry for all the illness from which the worker suffered. Dr. T. O. GARLAND suggested that it would be useful if industrial medical officers were given facilities for visiting condemned areas and new housing estates in their districts.

THE MEDICAL SOCIETY OF INDIVIDUAL PSYCHOLOGY

At a meeting of the Medical Society of Individual Psychology held on December 9, with Dr. H. C. SQUIRES in the chair, a paper was read by Dr. O. H. WOODCOCK on "The Contribution of Adler to Psychological Medicine: The Relation of the Sexes."

Dr. Woodcock said this subject was chosen as the third in the symposium on Alfred Adler because it had often been a criticism of individual psychology that Adler avoided the issue on sex, and that his concept of "the masculine protest" was merely to use another and inferior title to "the castration complex" of Freud. This indictment had little justification except that, in his revolt from the tremendous stress placed by Freud on sex, Adler had laid more emphasis in his writings on the subjects of the will to power and community (or social) feeling. He taught that an individual must adjust himself to life along three lines—namely, to society, to vocation, to sex—if a completely harmonious personality is to result. The biological urge of every living organism is to complete development characteristic of its species. In his unpublished lecture "Marriage as a Task" Adler described monogamy as the highest sexual goal for mankind, and regards it as a constructive task, requiring infinite patience and understanding, on the part of two people who have determined to enrich and relieve each other's lives. It is a task so difficult of achievement that many fall by the way, but those who survive discover a beauty that transcends all other human relationships. All sexual relations or attitudes other than mating founded on mutual affection and thoughtfulness are useless goals, fictive and demoralizing—the retreats of cowards, foolish short cuts of the lazy, and attempts at domination by the cruel and the egoistic. A sexual illness arose when one person used another only for his or her own profit. Adler said that masculine dominance was not a natural thing, yet all our institutions, our traditional attitude, our laws, our morals, our customs, give evidence of the fact that they were determined and maintained by privileged males for the glory of male domination. Hence the dissatisfaction with the feminine role and the adoption of what Adler called "the masculine protest." There should not be dominance on either side in the sex relation of male and female. Marriage was the highest expression of social feeling, in which the ideal aim should be "to give," and the requirements were exceptional ability to identify oneself with the partner.

Dr. Woodcock then went on to describe Adler's teaching with regard to what he termed the false paths, retreats, evasions, the perversions, the devices of those who have

failed to realize marriage as an exercise in co-operation with a partner of the opposite sex. With regard to such aberrations as masturbation, frigidity, impotence, ejaculation praecox, vaginismus, homosexuality, exhibitionism, fetishism, promiscuity, celibacy, prostitution, masochism, and sadism, Adler believed that many of these were difficult problems, but not insurmountable. The treatment of each would be determined, after analysis of the problem, in the consulting-room according to the methods of individual psychology.

There was an interesting discussion afterwards, to which many of the audience contributed.

OBSTETRICS AND GYNAECOLOGY

At a meeting of the North of England Obstetrical and Gynaecological Society, held in Liverpool on November 26, with the president, Dr. J. W. BRIDE, in the chair, Mr. BRIAN WILLIAMS (Liverpool) read a note on the use of protosil in obstetrics. In forty-four of the cases he had treated the haemolytic streptococcus had not been isolated, and in such cases there was no evidence that protosil was of value. In forty cases a haemolytic streptococcus had been found; in nineteen of these in which infection was localized there were no deaths; in ten where infection involved the pelvic cellular tissue, the peritoneum, veins, tubes, or ovaries there were no deaths; but of the eleven remaining patients, showing either septicaemia or peritonitis, six died. He administered the drug prophylactically to 104 patients, in none of whom were haemolytic streptococci found, whereas in seventy-three controls this organism occurred eight times. An interesting discussion followed in which Professor JOHN CHISHOLM (Sheffield), Mr. A. GEMMELL (Liverpool), Mr. C. WALSH (Liverpool), Mr. BURNS (Liverpool), and Mr. JEFFCOTE (Liverpool) took part. At the same meeting the president, Dr. J. W. BRIDE (Manchester), discussed further a case of malignant tumour of the ovary and lung in a girl of 12. Mr. C. J. K. HAMILTON reported a case of acute yellow atrophy of the liver; Professor A. M. CLAYE (Leeds) discussed a case in which dysmenorrhoea and dyspareunia were due to endometriosis; and Mr. GEMMELL showed two pathological specimens, one of carcinoma of the isthmus uteri, the other of a sarcoma of the uterus. Finally, Mr. ST. GEORGE WILSON (Liverpool) showed, by means of a cinematograph film, a method of delivering the trunk and arms in breech presentation.

A meeting of the London Association of the Medical Women's Federation was held on December 8 at the premises of Messrs. Hazell, Watson and Viney, Long Acre, W.C., printers of the *Lancet*. Small parties were conducted round the works and inspected processes of setting up copy by monotype machines; correcting errors of composition; making-up and imposition of pages; printing; and folding, gathering, and stitching. In the course of the evening Dr. M. H. Kettle commented on some editorial aspects of the printing arrangements. Some seventy members were present. In the unavoidable absence of the president, Miss E. C. Lewis, Dr. Letitia Fairfield thanked the directors for the opportunity offered to see the *Lancet* in the making, and for their hospitality.

A clinical meeting of the Oral Surgery Club was held at Leeds on November 26 and 27, twenty-six members and guests being present. The general meeting and dinner was held in the University Staff House on November 26. The following were elected to hold office for the coming year: president, Professor T. Talmage Read; members of committee, Professor F. C. Wilkinson, Major S. H. Woods, Mr. T. Hall Felton, Mr. A. E. Rowlett, and Mr. Harold Round; honorary secretary, Mr. R. S. Taylor.

which were, therefore, near the hilum and liable to show early spread to the glands at the hilum—not hopeful subjects for an attempt at surgical cure. If the growth was situated more peripherally so that the surgeon had a chance of removing one or more lobes through healthy bronchial tissue there was much more difficulty in making an early diagnosis.

Place of Surgery

Mr. JOHN T. MORRISON referred to fifteen cases in the literature of total pneumonectomy and thirty-nine of lobectomy. Of the former, six out of the seven survivors were claimed as cures; of the latter, so far as records went, at least nine out of the twenty-six survivors, and possibly more. There were among the lobectomies considerably more recurrences to offset the lower operation mortality. In assessing operability, Mr. Morrison set on one side the large number of growths involving the main bronchus, in which cases for the most part only palliative radiation therapy was feasible. He then went on to point out and illustrate radiologically the variability of atelectasis in relation to the size and position of the primary growth.

Drs. T. F. HEWER, G. A. C. LYNCH, and R. H. MOLE exhibited a series of specimens. Mr. J. E. G. MCGIBBON reported some favourable results of treatment with deep x-ray therapy, with or without the use of radon seeds, in a series of fifty-five cases of bronchogenic carcinoma in the bronchoscopic clinic of the Royal Southern Hospital. Dr. P. H. WHITAKER, Dr. J. H. MATHER, and Dr. E. T. BAKER-BATES also took part in the discussion.

PUBLIC HEALTH SERVICES AND INDUSTRIAL HYGIENE

A combined meeting of the Society of Medical Officers of Health and the Association of Industrial Medical Officers was held on December 17, when addresses, preliminary to a general informal discussion, were given by Dr. J. J. Buchan, medical officer of health for Bradford, and Dr. Donald Stewart, medical officer, Imperial Chemical Industries, on "The Public Health Services and Industrial Hygiene."

Dr. J. J. BUCHAN said that many cases of illness and accident in factories were in no very remote sense due to conditions arising outside the factory. This only emphasized the need for co-operation between these two services, and the first essential to co-operation was an understanding of each other's field and problems. One primary difficulty was that two different departments of State were concerned—the Ministry of Health in the case of the public health services, and the Home Office in the case of industrial health services. In his own area at least the Home Office was very commonly regarded as having for its province criminal jurisdiction rather than the common health, and this operated disadvantageously in some respects. Something of this feeling had crept into the law and practice of industrial hygiene in that there was a distinct tendency to blame industry for all illness that occurred among the workers. On the other hand, Dr. H. E. Collier of Birmingham University had said truly that industry ought not to be saddled with the cost of illnesses which were really attributable to faulty social conditions and communal ignorance. Dr. Buchan hoped the time would soon come when industrial workers would be subject to some degree of continuous hygienic supervision. It was by no means uncommon to find a young worker falling in health shortly after he had been drawn into industry. During this period of acclimatization to industrial conditions there ought to be closer supervision than at present. Something of this kind was attempted by the more enlightened firms, but it should not be considered that the whole cost was a proper charge on industry, nor should the arrangements be controlled by industry or by the Home Office. It had been the experi-

ence of many members of the public health service that employers, when faced with this problem affecting the health of their employees, did not hesitate to consult the officers of the local health authority. That had been his experience in his own city.

The certifying factory surgeon—now called the examining surgeon—ought, in Dr. Buchan's opinion, to have a less circumscribed position than he had to-day. He ought to be more than a mere certifier. The recent change of name was rather futile, because it still indicated that his responsibility was only for the medical examination; it did not imply any duty of continuous health supervision. He thought the arrangement whereby industrial medical officers might have access to school medical records was likely to prove of great value, and it was surprising to find that any doubt existed as to its utility. The school medical record gave impartial and reliable information of profound importance to those who had to do with health in factories. The records were compiled at a time when they were little likely to be influenced by the desire of the parents to find employment for the children, and if made by careful and understanding school medical officers and read by officers of a like kind in other services they were likely to be extremely useful. His own school records were referred to continually in the juvenile employment bureau, as well as in juvenile and ordinary courts and elsewhere.

Dr. DONALD STEWART said that both the public health and the industrial health services aimed at prevention, and had comparatively little to do with curative measures. The general practitioner had been much against them both, and the word "encroachment" had been heard with regard to both, but he believed that that day was over and that the general practitioner now was willing to be helped, and officers in these services were more than willing to help him. In what way were the public health services developing? So far as the public health services were concerned there was ample evidence of extensive development, as was shown by the reports of the central and local authorities. The development on the whole appeared to be satisfactory, but he had one or two criticisms—for example, the public health services did not pay sufficient regard to such matters as housing, recreation, and social amenities. The Factory Department of the Home Office had developed slowly but efficiently, and had lately been concerned in some extremely good work in connexion with the rehabilitation of persons injured in accidents, and, still more recently, in the question of lighting in factories.

The 1,700 industrial medical officers known as factory examining surgeons (Dr. Stewart continued) were a much maligned body of men, but he believed their activities should have wider scope. Again, the Industrial Health Research Board was in its own sphere the finest thing in the industrial medicine of other countries. The bridging of the gap between actual research and the application of it in the workshop, factory, and office was a problem which would have to be solved before any industrial service became fully effective. Another respect in which the industrial health service had advanced was in relation to injuries. The industrial medical officer, whole- or part-time, was necessary to-day even from that one angle alone, to prevent lost time through "stupid things like sepsis," and to aid in the effective rehabilitation of the injured workman. Research was necessary also into industrial working conditions, the comfort of the worker, and the psychological effect of groupings of workers. One of the outstanding questions was to "get across" to the employer the sane medical outlook with regard to his workpeople. In order to obtain the best results the industrial medical officer must be in closest contact for a large part of his time with the employer. He had to be a part of the management. As for the worker himself, he, through his organizations and trade unions, had a very definite interest in the contribution that medicine could make.

Correspondence

Immunization against Typhoid

SIR,—I am in complete agreement with Professor Greenwood regarding the fallacies inherent in such statistics as those of typhoid immunization. This is especially so when the figures are compiled by medical men who are not necessarily expert statisticians. It is, however, possible to obtain a broad impression which, although not having the value of accurately compiled statistics, makes a reasonable appeal to common sense.

From the beginning of the war I had charge of the campaign against typhoid among both troops and civilians in Alsace and in some parts of the adjacent French territory. In these regions typhoid was endemic, and many cases occurred among the German troops when they were billeted in the villages. In spite of all efforts both before and after the beginning of the war—which efforts included the isolation of all bacilli carriers—typhoid continued to occur among the civil population, but not among the troops who had been vaccinated. It was therefore decided to enforce vaccination upon the civil population in a district where the disease had been prevalent for more than thirty years. After this vaccination no case of typhoid occurred in that district for the remainder of the war, and we were informed by the Civil District Medical Officer that this was the first time that this had happened. This was so much more surprising in that general conditions were much worse than during peace time.

After the war I received a grant from the Prussian Ministry of Health for the purpose of the study of oral immunization. There are two methods of oral immunization: the first is that of Besredka, where bile pills are given before the tablet of oral vaccine; and the second is that of von Wassermann and Neuberg, where sodium benzoate is used in place of the bile pill. Up till January, 1927, Besredka's method had been used in about 250,000 cases in both French territory and in Eastern Europe, good results being obtained in both places. In the town of Lodz, of 43,000 immunized people only forty-three became infected (0.1 per cent.), while among the 73,000 non-immunized people, 1,000 cases occurred (1.4 per cent.). In the last edition of his book (1937) Besredka gives further examples of the good results obtainable: 32,130 received vaccine, and there were six cases of typhoid; among 45,790 controls there were thirty-nine cases of typhoid. In an investigation carried out in Japan it was observed that in Tokyo, out of 42,094 who had received vaccine there were 229 cases of typhoid, and that out of 154,390 controls 1,624 developed typhoid; in rural districts, out of 77,810 who were given vaccine 306 subsequently developed typhoid, and in 267,109 controls there were 2,929 cases.

A report by Tchernozoubov showed that monovalent oral vaccines prepared from about 12 strains gave complete protection, no case after that occurring in three villages with populations totalling about 2,000 inhabitants. He stresses the advantage which lies in the fact that as many as 50,000 million organisms may be administered by this method, whereas no more than half this number may be injected. The fact that after oral immunization the Widal titre rises to 1:1,000 or 1:1,200 and remains as high as 1:200 or 1:400 after ten months shows that the antigenic properties are resorbed and are present in the circulation (Ruge). The method of von Wassermann was

used in Germany and Jugoslavia. Hirsch (Jugoslavia) immunized 350 people by mouth, of whom not one became infected, while nine cases of typhoid occurred among 500 people of the same district who were not immunized; there were two cases among 2,000 people immunized subcutaneously. Mantey (Germany) carried out investigations in a city of 5,000 inhabitants where typhoid was endemic, and where 220 cases had occurred in four previous years. He gave oral immunization to 178 people who had been in contact with typhoid cases or carriers, but, despite this "isolation," two cases occurred among people who had not been immunized.

Apart from these examples the method was used in the Hanover outbreak in 1926, when 20,000 people were given oral immunization, but, as the method was not used until the latter part of the epidemic, no conclusions can be drawn from the protection obtained. The number included some hundreds of school children, and no complaints were received of any ill effects or reactions.

I feel that the method is worthy of trial in other instances, and that it is especially useful under the conditions of peace and among a civil population where the opposition to injection prevents the use of subcutaneous vaccination. It further avoids the inconvenience of those reactions which frequently follow the injection technique.—I am, etc.,

London, W.1, Dec. 21, 1937.

ERNST M. FRAENKEL.

Periodicity of Recurrences in Cancer

SIR,—The theory of a thirty-three-week cycle in epidemics of influenza, advanced by Brownlee and by Stallybrass, has been found useful in forecasting epidemics. Its essential nature, however, remains undetermined, possibly depending on some life-cycle of the causal virus. Many writers have pointed out that exacerbations of malignant disease often follow attacks of influenza, tonsillitis, etc., but so far as I know no periodicity has been reported in recurrences of malignancy. The following observations suggest, however, that this does occur in breast cancer in thirty-three-week cycles.

In twelve patients (private cases) with breast cancer who have been followed up carefully at intervals of one to three months (some for periods of four or more years) recurrences have been noted at thirty-three-week intervals. In one patient four such periods have been observed with recurrence of nodules in the scar and metastases in the opposite breast and axilla. In twenty hospital patients in one series examined the same phenomenon was apparent in primary, recurrent, and metastatic cases. Most patients showing "cyclical or intrinsic periodicity" (Stallybrass, C. O., *Principles of Epidemiology*, 1931, p. 570) clearly had a thirty-three-week cycle, sometimes singly, or in longer periods with two to nine cycles between the appearance of recurrences. Thus two-year periods of intermission were occasionally noted—that is, three intervals of thirty-three weeks.

A similar periodicity of seven and a half to eight months has been traced in thirty other cases of cancer in other sites—for example, skin, lip, cheek, palate, tongue, pharynx, larynx, oesophagus, and testicle. A preliminary survey shows a great majority of recurrences at this interval. Also in the allied diseases, Hodgkin's disease and leukaemia, several instances have been found in the few cases tested. One patient with Mikulicz's disease had three periods.

Periodicity is a phenomenon of recurrence and cannot be found either in patients rapidly cured, in those dying soon with a highly virulent invasion, or in those with very low resistance. Further points for study are the

Local News

ENGLAND AND WALES

Vital Statistics for 1936

The volume of Medical Tables forming Part I of the Registrar-General's Statistical Review of England and Wales for 1936 (H.M. Stationery Office, 6s.) shows that the number of live births registered during the year was 605,292, giving a birth rate of 14.8 per 1,000 persons living. This rate was 0.1 above that for 1935, and 0.4 above that for 1933, which was the lowest ever recorded. The county having the highest rate was Durham with 17.3, followed by Staffordshire with 17.0; those with the lowest rates were Cardiganshire 11.7, Cambridgeshire 11.9, and East Sussex 11.9. The death rate was 12.1 per 1,000 persons living, 0.4 above the rate for 1935 and 0.3 above that for 1934, but 0.2 below that for 1933. When allowance is made for the fact that the average age of the living population is increasing every year, the resulting corrected or standardized death rate was 9.2, which is 0.2 above that for 1935, the lowest ever recorded both for men and for women. The mortality of infants under 1 year was 59 per 1,000 live births, which is 2 per 1,000 in excess of that for 1935, the lowest on record. Mortality from infectious and parasitic diseases in general reached a low record of 1.17 per 1,000, and the tuberculosis death rate declined once again to a new low record of 692 per million. Pneumonia mortality was 690 per million—only a slight increase on that for 1935, the lowest recorded. The measles death rate per million children under 15, which up to twenty years ago was seldom below 1,000, was 297, and the whooping-cough rate was 228. Diphtheria again registered a considerable improvement over the preceding year. The cancer rate, corrected for the increasing age of the population, increased slightly to 1,010 per million from 1,001 in the previous year. Deaths of women attributed to complications of child-bearing numbered 1.34 from septic causes and 2.31 from other puerperal causes to each 1,000 live and still births, compared with rates of 1.61 and 2.33 respectively in 1935. Resort to suicide showed a further decline, the crude rates per million persons living having fallen each year since 1932, when the high level of 143 was reached, by successive steps to 124 in 1936. Accidental deaths by fall or crushing, including traffic fatalities, increased to 306 per million, which equals the high record of 1934.

Science and Social Service

In his address on science and social service given to members of the National Institute of Industrial Psychology at Burlington House, London, on December 16, Sir Richard Gregory, Bt., editor of *Nature*, stressed the urgent need for the application of scientific method to social and international problems. Although scientific discoveries might be prostituted in the cause of war, it must be acknowledged that the advance of science had on the whole led to an enormous alleviation of human suffering and an increase in the capacity and facilities for happiness. As science was responsible for the industrial developments and economic changes which had caused also the means by which civilization might commit suicide, it had a duty to guide the human race in the wise use of the powers it had created. The personal and group loyalties of men, their fears, ideals, passions, and ambitions, all lent themselves to scientific study with a view to providing a basis for effective social action. It was fashionable at the present time to blame the machine for the mechanization of life. To do this was to make the fundamental mistake of

regarding the machine as the master and not the servant of society, and to forget that the most regrettable results of industrialization were not for the most part the direct fault of technological progress, but of lack of consideration for human needs. Science should be able to assist in the solution of problems arising out of the new social environment as well as in the industrial field. One of the prime needs of the present time was the development of research in the social and biological sciences on a scale commensurate with that of the physical sciences. In contrast to investigations which treated human beings as mechanical robots the primary aim of any such studies should be to increase the comfort and promote the intelligence of the worker in order to combat the evils due to conditions arising out of mechanization in industry. Most of the work of the National Institute of Industrial Psychology was designed to this end, and was thus assisting in the adjustment of society to the changes caused by technical development. In conclusion Sir Richard Gregory referred particularly to the value of the Institute's work in vocational guidance and selection.

Midwives and Cases of Contracted Pelvis

At the December meeting of the Central Midwives Board for England and Wales a letter from the Central Midwives Institute was considered. It asked for a ruling as to whether, under the existing rules, if a midwife is advised by the doctor in charge of an ante-natal clinic that her patient has a contracted pelvis and that a doctor should be engaged, the midwife is obliged to act on the advice given or whether she may decide for herself if the pelvis is contracted or not, and whether it is necessary to engage a doctor. The Board decided that a reply be sent to the Midwives Institute in the following terms:

Except in an emergency a midwife must not, without medical aid, attend a pregnant woman or conduct a confinement if the patient is suffering from any abnormality or complication. If a midwife has been notified by a registered medical practitioner in charge of an ante-natal clinic that one of a midwife's patients has a contracted pelvis or other abnormality, and that a doctor should be responsible for the care of the midwife must act in accordance with the notification of the such medical practitioner. In the opinion of the Board, any notification of the nature referred to above should be made by the medical officer in charge of the ante-natal clinic in writing, and not verbally.

Physical Education and Training

A conference on physical education and training, arranged by the London Head Mistresses' Employment Committee, was held recently at Montagu House, Whitehall, the headquarters of the Ministry of Labour. Miss E. Strudwick, High Mistress of St. Paul's Girls' School and chairman of the Employment Committee, presided over a meeting of head mistresses and physical training teachers. The principal speakers were Miss D. Spafford, secretary of the Ling Physical Education Association, and Sir Henry Pelham of the National Advisory Council for Physical Training and Recreation. Other experts contributing to the discussion were Miss Colson of the Central Council for Recreative Physical Training, Miss Grant Clark of the L.C.C. College of Physical Training, and the principals of physical training colleges. Miss Spafford said the shortage of trained gymnastic teachers had been accentuated by the demand for trained organizers in all parts of the country, due to the popularity of recreative physical training. Speaking of the three years' course, she emphasized the value of the third year of training, which included a medical course and dancing. In the field of recreative physical training Miss Spafford emphasized the need for a thorough and all-round training. Miss Strudwick, referring to the demand for shorter courses of training, spoke of the danger of lowering the high standard which had been achieved by physical training colleges in the past.

The "lucubration" of his readaptation may go on for weeks without further intervention of the psychotherapist, who should never adopt the role of priest, but assume that of a fellow searcher, who does not impose upon him but draws out potentialities for autochthonous development. For the human psyche is not a static automaton, but a dynamism for illimitable adjustment to ever-changing circumstance. For, however standardized and automatic become the processes of industry, there always remains the difficult problem of social adjustment, demanding a complex selectivity, the failure of which is the most fertile source of psychoneuroses even in industrial relations, as has been shown by Elton Mayo in America and by Charles Myers and his co-workers in England.

That the patient must learn to understand thoroughly the inner processes of his mind excludes from psychotherapy the claims of the cults, medical or lay, which appeal esoterically or by side-tracking the real issue by substituting for it a panacea. Equally barred is suggestion, the most rapid method of all, the essence of which is that the patient does not understand the process. Enlightenment is the prime essential if fresh stimuli, unavoidable in ordinary life, are to be evaluated correctly. For example, in a kleptomaniac seen last month a single interview sufficed for ascertaining that the patient stole because of a resentment against a world which had crippled him by stealing from him. The irresistible impulse to steal ceased with his reorientation towards its cause; whereas appeals to prudence and morality had led only to an attempt at suicide.

In thirty years' practice of psychotherapy I have encountered only four cases which approached the large number of hours assumed necessary by your correspondent Dr. Fretson Skinner (December 11, p. 1196).

The first case, nearly thirty years ago—an anxiety hysteria due to marital maladjustment—was under treatment for two years, owing entirely to my own lack of experience and blundering. The second, a writer's cramp, required six months. Each of these patients was sent away for a long change during treatment, however, so that in neither did it actually consume over twenty hours. The third was a case of paranoid interpretations, despair, drug and alcohol addiction, and a determined attempt at suicide. Reorientation was effected by daily interviews for six weeks—about fifty hours. This 30-year-old failure is now embarked on a successful career. The fourth, a 60-year-old woman with paranoid attitudes, was seen about five times a week for nearly six months. She has remained well for six years.

These are conspicuous exceptions, for the usual patient seldom needs more than a week or two for permanent reorientation, and seldom requires as much as five hours of actual psychotherapy. I know of only one relapse, and that occurred after fifteen years of successful professional life.

The aim at the essentials of reconditioning avoids time-consuming and seldom advantageous free association, dream analysis, the bedevilment of a supposed sexual origin except when present, the seeking for non-existing repressions except when there, and all reference to a hypothetical unconscious and suchlike red herrings, which obscure the issue, waste hours, and mystify the patient and often doctor also, when they are not mere devices for the deep anamnesis necessary to penetrate the inner psyche of the patient.

Neither Faculties nor practitioners can be blamed for scepticism towards methods which claim esoteric exclusiveness, such as requiring that an exponent be psycho-analysed by Freud. It is significant, too, that the leading English-speaking advocate of that form of psycho-analysis, Dr. Brill of New York, confessed before the American

Psychiatric Association in 1926 that it cured few even of the small number of psychoneurotics who should be psycho-analysed. This was in marked contrast to the claims of himself and others in 1901, after the introduction of the method to America—that all psychoneurotics were curable by this method, and by this method only.—I am, etc.,

Bordighera, Dec. 18, 1937.

TOM A. WILLIAMS.

SIR,—I was greatly heartened to see two letters on this subject in the *Journal* to-day, particularly when they are written by such well-known authorities as Dr. Ross and Dr. Rees. Perhaps I may be pardoned for a little loose exaggeration in my effort to state some of the difficulties I have personally met with in the treatment of psychoneurotic cases.

I have neither the skill nor the experience of Dr. Ross, whose pioneer work is known and valued by all who are interested in this subject, and the last thing I wish is to create discussion on the methods of treatment or schools of thought. I should have said there are "not many guide-posts" rather than "not any." But my point was that most medical men are sent out from the schools without much knowledge as to the whereabouts of these guide-posts, and without the skill to read them when they are met with.

It must, of course, be true that many cases of the milder types of psychoneurosis *do* get well in less time than I mentioned. Every medical man uses his personality in treating his patients, and those neurotics who get well do so because of the "unconscious psychotherapy" employed by the hard-worked doctor. It was not of these cases I was writing, but of the more serious cases that constitute such a difficult group. For example, the anxiety states seen in miners form a very big group of cases in my clinic. These men are truly pitiable, in that they really want to return to work but cannot do so on account of their anxiety, seen under its varying symptomatology. Then again there is the group of "difficult youths" who are unable to find an occupational niche. This is the result of the economic stress during the "slump" period, which produced a home environment which, in spite of brave and gallant endeavours to prevent it, tends to lead to childish reaction character traits and psychoneurotic disorders. It is these groups among others that form such a difficult problem in big industrial cities like Sheffield. To quote Dr. Ross himself (*The Common Neuroses*):

"Such a patient if taken on at all must be taken seriously; the first interview is one of the most important of all, and if a patient turns up with the symptoms which suggest the presence of a functional state and the doctor is pressed for time, he should defer the taking of the case *till he has at least a full hour to spare*." (Italics mine.)

This is exactly the difficulty I tried to stress. To wait for a full hour for six patients seen on the one day a week devoted to the clinic means setting aside six hours during the week for these people. To give them only six interviews is to spend thirty-six hours over six patients, and meanwhile there are another six new patients each week to be similarly dealt with. It is merely a matter of arithmetic to see that a waiting list very soon becomes choked.

I think the suggestion put forward by Dr. Rees—namely, that of a special committee to be set up by the B.M.A.—is worthy of the closest consideration.—I am, etc.,

Sheffield, Dec. 18, 1937.

E. FRETSON SKINNER.

relation of irradiation to periodicity: as to altering its spacing or not, as to radiosensitivity at stages of a period, and as to the possible value of prophylactic irradiation (local or general) just before a probable period of recurrence. Clinical examination would appear to be most necessary at and about the periods of maximal growth activity, as the earliest recurrences respond most satisfactorily to treatment. Periodicity might be studied with advantage to our knowledge in those few patients who refuse all medical treatment, for about untreated cases little is known so far but the average duration of life. Biochemical research at maximal periods might yield valuable results.

As to explanations of periodicity the most probable appears to be that it supports the virus theory of cancer. I have lately discussed some of the evidence in favour of it (*Brit. J. Radiol.*, 1937, 10, 529), such as contagion and possible association with other virus diseases. If periodicity be established as part of the natural history of tumours it would appear to support the virus theory of their origin: the dates so far assembled appear to be random ones, not following the influenza maxima, as the alternative explanation of a lowered resistance to malignancy resulting from influenzal infection (manifest or latent) would seem to imply. Detailed statistics will be published in due course. The study of periodicity may be expected to throw new light on the cancer problem from the points of view of the clinician, the medical statistician, and the pathologist.—I am, etc.,

Lipoids and Cancer

SIR,—In an annotation in the *Journal* of December 18 (p. 1229) on the nature of the Rous agent; you draw attention to the work of Jobling, Sproul, and Stevens, who have successfully obtained from the Rous tumours active carcinogenic extracts, which contain very little proteid or carbohydrates, but consist mostly of lipoids, and you question whether these facts have any relation to the chemical structure of known carcinogenic compounds.

That lipoids are in some way associated with the onset of malignant disease has been suggested from time to time—for instance, Cronin Lowe, in discussing the Bendien reaction, has pointed out the deficiency of the lipolytic power of the serum, and Shaw MacKenzie has done some valuable work in this connexion. But we have not advanced much further. It seems to me that in cancer there is a disturbance of the lipoid metabolism, which brings about an alteration in the surface tension of the cells, causing them to proliferate unduly. It is in this alteration of surface tension that the mysteries of the division of the cells and nuclei lie. In mitosis and after fertilization the protoplasm becomes converted to a more or less jelly state; this change is always an indication of activity. I believe that in cancer there is in the serum and tissues an excess of non-saturated fatty acids or of alkalis, or perhaps of both, and these combine to form saponins, which have a profound effect on surface tension. Indeed, it is known that such an increase in fatty acids does occur, the percentage rising from 62.1 in health to 72.62 in cases of cancer. According to W. E. Dixon, the key to the understanding of the action of the saponins lies in their behaviour to cholesterol and lecithin, with which they combine in equimolecular amounts; the

lipoids of the cells are then changed physically and chemically and lose their functions. Thus the lipid membrane of the red blood cells loses its power of retaining the viscous haemoglobin, which passes out of the stroma. Have we not here an explanation of what occurs in pernicious anaemia which is successfully treated by the exhibition of the liver esterases, with their action on fatty acids? There is no doubt that the cohesion of protoplasm is due to the fats present, and anything affecting this cohesion causes an alteration in the physical state of the cells, and thereby an alteration of surface tension.

Cholesterol exists in the body combined with fatty acids as esters, which in health are split, dissolved, and hydrolysed by the esterases of the bile, duodenum, and pancreas (Thamhauser). From esters it is not a far step to the production of carcinogenic bodies. All that is required is their dehydrogenation by a faulty mechanism, and we know that in cancer there is a diminution in body acidity; we also know from the experiments of Loeb, B. Moore, and others that an increase in alkalinity stimulates, and an increase in acidity depresses, manifestations of cell life. Dehydrogenation of esters may be explained by this statement of B. Moore: "It is clear that the rate of production of acids, other things being equal, must depend on the concentration of hydrogen ions in the plasma. A drop from any cause of hydrogen ions in the plasma must mean a corresponding fall in the rate of production of acids."

There are, then, five conclusions: (1) cell division is affected by an alteration in the surface tension; (2) faulty metabolism of lipoids causes an alteration of surface tension, most probably from the formation of soaps; (3) diminished acidity stimulates growth; (4) in cancer there occurs diminished acidity due to a drop in the hydrogen ions of the plasma; and (5) dehydrogenation of esters causes them to become carcinogenic.—I am, etc.,

Wigan, Dec. 22, 1937.

J. THOMSON SHIRLAW,

Treatment of Psychoneuroses

SIR,—As the essence of psychoneuroses is an emotion preventing a due adjustment of circumstance, then in order to get rid of it the means of its induction must be sought. The principle of their conditioning in human beings does not differ from that used by Pavlov in dogs, where by artificial stimuli he produced in the animals a state of expectation of food which led to the physiological reactions normally set up by its presence. Similarly he showed how to induce by an artificial stimulus the physiological consequences of such an incommensurate emotion as fear, which with human beings is the most frequent emotional factor in psychoneuroses, whether expressed as specific phobia, general anxiety, obsessive thinking, sense of inadequacy, faulty interpretations, excessive rationalizations, or even some mannerisms. In the dog a reorientation of attitude towards the artificial stimulus reconditions its effects, so that a sound that had produced the tremor of fear will now produce salivation and pleasure of food expected.

Psychotherapy is essentially a reconditioning on this principle. It is reorientation of a patient's attitude, so that stimuli which had made him uncomfortable become indifferent or pleasurable. The more simply this is attempted the less time it takes. Indeed, when a single external situation provokes a phobia, paralysis, anaesthesia, mutism, an emotional crisis, or what not, reconditioning may require only one interview. But it will seldom be permanent, unless the patient learns the rationale of the process whereby his life attitude is re-set.

the aortic valves there was a vertical tear about half an inch long through an atheromatous patch. The coats of the aorta were separated to form a dissecting aneurysm, and from this there was an opening into the pericardial sac. The heart was not enlarged, and the other organs of the body appeared to be normal.

In both Miss Ottley's case and my own sudden pain was experienced. In the former it was referred to the epigastrium, in the latter to the chest, and in both cases it radiated to the back. My patient had the definite feeling that something had given way; this does not appear to have been experienced by Miss Ottley's case. Both patients were pale, in both the pulse was regular and slow and the blood pressure readings similar. In both cases a primary rupture took place forming a dissecting aneurysm, which was followed by the secondary rupture, in Miss Ottley's case in some seven hours' time and in mine in about twenty-seven hours. Both were married women, Miss Ottley's patient being 63 and mine twenty-six years younger.

I am indebted to Lieutenant-General Sir James A. Hartigan, Director-General, Army Medical Services, for permission to publish these notes.

—I am, etc.,

London, E.4, Dec. 13, 1937. R. W. SWAYNE, M.B., B.S.

An Easy Method of Venepuncture

SIR,—Two of the commonest difficulties encountered in venepuncture are complete transfixion of the vein and the excessive mobility which accounts for the failure to enter it. These difficulties are met with especially by practitioners who have to do only a few venepunctures a year.

1.—Superficial radial vein. (2) Median cephalic vein.
3.—Median basilic vein. 4.—Superficial ulnar vein.

To overcome them I have devised the following technique, which I have used in a large number of cases with complete success, even where the veins have been very small. The principle of the method is to aim at the angle formed by the junction of two veins—that of the superficial radial and the median cephalic, that of the median basilic and the superficial ulnar, or any other junction which may present itself about the elbow-joint. By this technique slipping is prevented; the chances of entering a vein are greatly increased, as there is one on each side of the needle; and the danger of going through the vein is minimized. I have found this method particularly valuable in taking blood from donors for transfusion.—I am, etc.,

Ether Convulsions

SIR,—Mr. J. B. Bamford's comments on this subject in the *Journal* of December 18 (p. 1252) have reminded me that I had three cases of so-called ether convulsions when I was an anaesthetist to several of the smaller London hospitals thirty-five years ago. My colleagues called it ether convulsions, but I did not agree with them, as all the three cases were not completely anaesthetized when the convulsions occurred, and on changing over to chloroform, which in those days was not considered a safe procedure, the convulsions ceased and the operation was completed.

Afterwards I went carefully into the patients' histories, and found that they had all three suffered from *petit mal*. It is, I think, accepted that these patients take ether very badly but chloroform well. It would be of interest to hear if Mr. Bamford had also considered this point before coming to the conclusion that his four cases were really suffering from ether convulsions.—I am, etc.,

Chichester, Dec. 20, 1937.

A. M. BARFORD.

The Problem of the Final M.B., B.S.Lond.

SIR,—Dr. A. M. H. Gray's natural modesty did not allow him to give a complete view of transactions in which he has played an important part. Some years ago the Board of the Faculty of Medicine appointed a committee to report to it on medical grievances. This committee advised the Board to ask the Senate to authorize a full inquiry into the university curriculum. This proposal seemed, however, inadequate. Viscount Dawson, I think, exhorted the Board to take a wider view, to remember that the ancient universities of Oxford and Cambridge sent their medical students to London, and urged that it would be more statesmanlike if the three universities—and the Royal Colleges—took council together. This view commended itself to the Board. The late Professor Pembrey did indeed object that the Colleges, not being universities, should not be included, but he was in a minority of one, and the logical defect he pointed out was thought to have been cured by associating the Society of Apothecaries (a body which had examined general practitioners long before the Royal College of Physicians could so far condescend) with the inquiry. An expert committee was constituted, took evidence, and reported. The report was adopted in principle by the Senate, which instructed its chain of subordinate academic committees to revise the scheme of medical teaching and examination in London accordingly. This elaborate process was completed about thirteen months ago, and all seemed to be ready for the trial of a new system.

But the Board of the Faculty could wait no longer, the scandal was too gross; perhaps the Universities of Oxford and Cambridge, the Royal Colleges, and the Society of Apothecaries, excellent in isolation, were bad in combination; perhaps these new regulations, so painfully elaborated, would not cure the evil. What was to be done? Recalling the ancient truth that the half is sometimes greater than the whole, the Board decided to forsake the Universities of Oxford and Cambridge (and the Society of Apothecaries) and take refuge in the arms of the Royal Colleges.

It may be asked what these *corporations*, as distinct from those of their individual members who are teachers of the *university*, have to contribute to the solution of an educational problem. They do not represent the general practitioners of the country; their only corporate relation with general practitioners is by virtue of the fact that they

Autophytic Dermatitis

SIR,—The able and authoritative article by Dr. Henry MacCormac in the *Journal* of December 11 has induced me to call attention to an allied, but somewhat different, form of autophytic dermatitis. In those cases the injury inflicted on the skin is not intentional but autonomous. It may be done at times of stress or agitation, or it may be a habit of which the patient is unaware, but in any case it often results in a dermatitis produced by touching or rubbing the skin by a restless moving finger, or the conveyance of a superficial infection from one part of the body to another by the same agency.

A middle-aged lady with erythema of the face, while talking in the course of her consultation, could be seen constantly touching her face with one or other hand. She was quite unconscious of doing so, and even when she was told about it did not desist until her hands were held. When the habit was controlled the skin healed.

As an instance of the conveyance of infection by the restless finger, a case occurred where it seemed likely that a Monilia infection between the toes had something to do with the starting of a pruritus ani.

Such involuntary actions might, I suppose, be termed "release phenomena" by the psychologists.—I am, etc.,

Rothsay, Dec. 17, 1937.

J. N. MARSHALL.

Strangulation of Herniated Ovary

SIR,—I have been much interested in the letters recently published in the *Journal* (August 7, p. 265; November 27, p. 1102; and December 4, p. 1152) on this subject.

Inguinal hernia in female children is rare in all who are adequately fed and whose diet is well managed. In other words, it is rare in those who are plump, contented, and happy; more common in those who are thin and cry continually from indigestion, or who strain when their bowels act. Rickets, which balloons out the intestine, predisposes markedly to hernia. The absorption of fat lays bare the internal ring and takes all the "stuffing" out of the canal. Crying and straining raise the intra-abdominal pressure enormously, while rickets expands, and therefore thins out, the abdominal wall. The role of the gubernaculum and the canal of Nuck is important, but I think a good deal of rubbish is written about it. How the gubernaculum can pull the testis to the bottom of the scrotum, when the scrotum is not a fixed point, and not pull the bottom of the scrotum up to the external abdominal ring, I can never understand, but I can believe that it pulls or anchors the genital organ, testis or ovary, at the brim of the true pelvis quite near the internal ring. Having reached this spot it requires very little excursion to enter into the canal or fall over into the pelvis. For some weeks after birth the testicles can easily be withdrawn into the abdominal cavity if the inner part of the thigh be touched. In much the same way, I think, the ovaries might be made to descend along the inguinal canal if they could be manipulated. I conducted an investigation on small babies, and examined post mortem the inguinal region of about 150. In no case was the peritoneum attached to the abdominal wall in any way, and it was invaginated, by a probe, along the inguinal canal to the external ring. The descent of the ovary may be comparatively rare, but when it occurs there is always danger of strangulation taking place, not so much if it is left alone but after well-meaning efforts at taxis.

I used to teach students that all strangulated herniae in baby girls of less than 3 months old contained ovary

and not bowel. Strangulation of gut in female children at this time is excessively rare. The reason for this is obvious, for if the bowel comes down the neck of the sac is expanded over the entering and returning portion of the gut, as well as the omentum between the two tubes. It has therefore a more or less pyramidal shape which favours replacement. The ovary, on the other hand, once down, is in the position of a button through a buttonhole; it has a narrow neck and is extremely difficult to replace, but often if left alone will go back by itself. If ordinary taxis is applied by anyone who fails to recognize what the contents of the hernia are, strangulation is quite likely to follow.

The prolapsed ovary overlies the external ring, and if pushed upwards and outwards, as in ordinary taxis, is pushed over the narrowest part of the ring just at the bifurcation of the two pillars where the chance of replacement is smallest. Continual pressure or persistence in taxis will injure the ovary, swelling takes place, and incarceration and strangulation may start in the ordinary way. Taxis, to be successful in the case of the ovary, must be made in exactly the opposite direction to ordinary taxis; in other words, the ovary must be gently pressed downwards and inwards to the pubic spine over the widest part of the ring, so that the button will the more easily go through the buttonhole. I have demonstrated this, and felt the ovary suddenly disappear as if snatched away, so often that I am sure of the truth of this observation.

From the letters in the *Journal* I gather that the probability of an ovary being in a strangulated hernia of a female infant needs emphasizing, and the true method of replacing it needs to be taught.—I am, etc.,

DUNCAN C. L. FITZWILLIAMS,

London, W.1, Dec. 22, 1937.

Rupture of the Aorta

SIR,—In the *Journal* of November 13 (p. 966) Miss Constance Ottley describes a case of this condition. It may be of interest to record a similar one.

On June 25, 1933, a married woman, aged 37, was admitted to the Military Families Hospital, Tidworth, as a stretcher case. On the morning of the previous day she felt unusually well, and had proceeded to carry out a "large washing." About midday, when she had almost finished her work, she was suddenly seized with a violent pain in the chest and back, which caused her to cry out. She stated that just before the pain came on she experienced a feeling that something had point she was quite clear and volunteered the information. She was able to walk into the back yard to summon help. The patient was seen by Captain Bayley, R.A.M.C., shortly afterwards. His report stated that she was pale, but that the pulse was slow and regular. There was no dyspnoea. She passed a somewhat restless night, and was admitted to hospital at 12.30 p.m. the following day. She was then somewhat pale, but her appearance did not suggest that she was gravely ill. The pulse was slow and regular, the temperature was 99° F., and the blood pressure was 130/80 mm. Hg. There was no evidence of cardiac enlargement; a systolic murmur was heard over the base of the heart. The radial pulses were equal in volume, and the pupils were equal. The patient complained of pain in the centre of the chest which radiated to the back and the right side of the neck. She was quite clear in her mind, and spoke without difficulty. A possible rupture of an aortic valve was considered, and an injection of 1/8 grain of morphine was administered. She became more comfortable and dozed. At 3.40 p.m. she was suddenly cyanosed and died immediately.

At necropsy the pericardial sac was distended with blood and the aorta atheromatous. About one and a half inches above

of your correspondent's much-appreciated testimonial to the high standard of the West London Hospital teaching, it is hard to believe that an institution with such a large and experienced staff, and upon which so much public money has been spent, could not give even greater value to medical graduates in the future than has been possible at the West London in the past.—I am, etc.,

MAURICE SHAW,
Dean, West London Hospital
Medical School.

London, W., Dec. 18, 1937.

Who Owns X-Ray Negatives?

SIR,—The paragraph from your Paris correspondent in the *Journal* of December 18 (p. 1246) raises this question again, and I am not aware of any definite judicial decision having been declared in this country as to whether ownership vests in the radiologist, the general practitioner, or the patient.

Unfortunately, radiologists are not uniform in their procedure, and it is conceivable that the looseness observed may create difficulty in the future if and when the opinions of the courts are sought by some zealous patient. For example, some radiologists send their films and report to the general practitioner without any intimation concerning the ownership or any request for return. The practitioner, equally careless, passes them on to the patient. In other instances the practitioner retains the films as part of the confidential report supplied by the radiologist, and also for his protection in the event of any litigation ensuing. Again, in some cases the radiologist will send a film direct to the patient without making any express contract stating in whom the ownership vests.

The importance of some uniformity in procedure is obvious, and it would strengthen the radiologist's position materially if the custom were established of supplying only the patient's medical adviser with the film and report, and intimating that possession vests in him, the radiologist.

The radiologist, like the biochemist and the bacteriologist, and possibly others in a team, contributes his skill as an aid to diagnosis, and it is the opinion based upon such skill and knowledge alone for which payment is made, and not anything tangible such as a mere photograph. It must nevertheless be clear that the non-medical radiographer who receives an order direct from a person merely to take a photograph of some particular region, and not a request to make a diagnosis, is an entirely different proposition. Here it may be held that payment is made just for work done in producing an x-ray film or print, and not for the expert professional opinion expressed in a report, which is based upon the technical interpretation of a skilled medical radiologist.—I am, etc.,

Bournemouth, Dec. 20, 1937.

WALTER ASTEN.

*• The question of ownership of x-ray films was discussed in the *Journal* of January 13, 1934, by a medico-legal correspondent, who was unable to trace any English legal decision on this point. He quoted three cases in the United States in which judgment had been given against a patient. In one of these it was decided that the films in dispute had no intrinsic value, and the court found that it was customary for the physician to retain the films as part of the records. Our correspondent said: "The point that the films had no intrinsic value seems sound as expressing the view that the patient pays for service and skill only." In one of the other cases, in which the patient had refused to pay a hospital bill unless the films were delivered to him, the court held that the patients bought and the hospital sold knowledge and experience,

not the material of an x-ray film, which was the property of the hospital. This and other medico-legal articles which had appeared in these columns were published in book form by Edward Arnold and Co., under the title of *Legal Problems in Medical Practice*, by D. Harcourt Kitchin.—Ed., *B.M.J.*

Auguste Forel and His Work

SIR,—I am sorry Dr. J. D. Rolleston disapproves so strongly of my review of Auguste Forel's autobiography. I tried to convey something of the vivid personality of the man as revealed therein, of the way in which he overcame early repressions and later opposition. I thought this would be more interesting to your readers than a list of laudatory references such as is contained in Dr. Rolleston's letter. Can I fairly be accused of failing to appreciate the greatness of Forel in writing such sentences as: "From a series of valuable observations on the structure and functions of the brain he was led to take up psychiatry, in which he made a name so soon that at the early age of 31, etc."; "a practical reformer achieving useful results"; "a single-minded fighter to the last for the truth as he saw it"; "his best memorial will be his work for psychiatry"? My "few slighting words" on his campaign against alcoholism are, presumably, "he never seemed to think that alcoholism was a symptom—for him it was a prime cause." Surely alcoholism is generally regarded to-day as a symptom of psychological or social disorder? I apologize for calling Forel a Bolshevik and will substitute anti-Tsarist. As for omitting any reference to his cerebral thrombosis, I put one into my original draft but cut it out for reasons of space. It is impossible to give a complete summary of a long and full life in the compass of a review. One must select those aspects which one found interesting and thinks may interest others. No two readers will see a pen portrait exactly alike. I might even disagree with the review Dr. Rolleston would have written; but I would assure him, on this appropriate date, that I had no intention of depreciating a great man whose work I have admired but of whose personality I was unaware until revealed by himself.—I am, etc.,

London, W., Dec. 25, 1937.

examine and license many, at a profit of £16,000 a year. It may be that the President of the Royal College of Physicians has wisdom to impart to a Viscount Dawson of Penn who is a representative of the Faculty of Medicine on the University Senate. It is just possible that the wisdom of Dr. Gray, a member of the President's Advisory Committee, will mellow the fiery eloquence of Dr. Gray, a senator of the University. But these seem rather metaphysical arguments. Until something more solid is produced, the Graduates' Association will not be alone in viewing with suspicion the gyrations of the Board of the Faculty of Medicine.—I am, etc.,

Loughton, Dec. 27, 1937.

MAJOR GREENWOOD.

Applying for Hospital Posts

SIR,—I am sure that everyone who has applied for a post on the honorary staff of a hospital will agree wholeheartedly with Mr. Kenneth Walker. Most of these elections involve a tremendous waste of time, particularly for the candidates. Personally I bitterly regret the hours which I have wasted in calling upon electors. It is high time that a committee was appointed to look into the whole system, with particular reference to the wording of the advertisements which invite application.

At the Cook County Hospital, Chicago, election to the staff is by examination conducted by an impartial body drawn from all parts of America save Chicago, and the appointment is for seven years. At the end of seven years every member of the staff must re-enter into open competition. Such a system has obvious advantages, both to the hospital and to the staff as a whole. In my opinion this is the fairest and most efficient system of election that has yet been devised.

The seven-yearly examination has recently taken place, and it might interest your readers to see the surgical paper.

CIVIL SERVICE COMMISSION OF COOK COUNTY ORIGINAL ENTRANCE EXAMINATION—No. 1471

ATTENDING STAFF—COOK COUNTY HOSPITAL

SURGERY

Class A. Rank 2. Grade 1.

Special Subject: Weight 5.

1. Discuss the types, symptoms, and treatment of diaphragmatic hernia.
2. Discuss appendicitis in children.
3. Discuss the aetiology, symptoms, complications, and treatment of gastro-jejunal ulcer.
4. Give the indications for exploration of the common bile duct during operations on the biliary system.
5. Discuss "water balance" and the methods to maintain it post-operatively.
6. Discuss causes, diagnosis, and treatment of palmar abscess.
7. Differentiate as to diagnosis and treatment between mechanical and paralytic ileus.
8. Give the symptoms, pathologic physiology, and treatment of a traumatic fistula between the femoral artery and vein at the level of Hunter's canal.
9. Discuss malignancies of the thyroid gland.
10. Discuss the symptoms, diagnosis, and treatment of carcinoma of the right colon.

—I am, etc.,

London, W.1, Dec. 17, 1937.

HAMILTON BAILEY.

West London Post-Graduate College

SIR,—I am sure that all my colleagues at the West London Hospital would wish me to thank your correspondent, "Postgraduate" (December 18, p. 1251) for his generous tribute to the value of the work of the West London Post-Graduate College. We share his regrets at the prospect of its passing, although these regrets are to

some extent softened by the birth of the new medical school which is to take its place.

If "Postgraduate" will read the detailed account of the history of the new school which appeared in the *British Medical Journal* on December 4 (p. 1124) he will appreciate that our policy has been largely forced upon us by circumstances outside our control. When the British Postgraduate Medical School was in process of formation some ten years ago it seemed natural that it should be established at the hospital which had, for thirty years, devoted itself exclusively to this branch of medical education. The School was, in fact, offered to the West London Hospital and the offer was accepted. Some months later the offer was withdrawn, to the detriment of our Hospital and College, as was fully explained in your article to which reference has been made.

In 1934 the new Postgraduate School, which had originally been promised to us, was about to open almost on our doorstep. Staffed by men of the greatest eminence and equipped and maintained by the unlimited resources of the State, the British Postgraduate Medical School seemed a grave menace to the future of the West London College, whose income was derived solely from students' fees and whose staff consisted of busy consultants with only limited time available for teaching purposes.

Our present action is therefore the natural outcome of past events. Although many thousands of postgraduate students from all parts of Great Britain, the Empire, and foreign countries have passed through our college no official encouragement or recognition was forthcoming until the idea of the British Postgraduate Medical School began to mature. The fulfilment of that scheme, at first so full of hope for the West London, ended by threatening the very existence of its College. In self-defence we had to consider other spheres of educational service, as we fully realized the great value to a hospital of some form of teaching activity.

"Postgraduate" asks why the West London should be chosen for the new medical school. If the need for a new undergraduate school is admitted, there could be no better argument in favour of its present location than his own flattering comments on the work of our Post-Graduate College. The establishment of a new school at a hospital without teaching experience or traditions would offer great difficulties, and, just as the West London once seemed the obvious place for the official Postgraduate School, so now its destiny seems to point no less clearly to a future of undergraduate teaching.

I do not think it is either practicable or advisable to teach graduates and undergraduates in the same institution unless entirely separate classes can be organized, and this would be impossible at a hospital of the size of the West London, and of which the clinical staff are all engaged in private practice. When the number of undergraduate students has increased to a substantial figure—and the applications indicate that this may be sooner than we once thought—it will be necessary at first to limit the entries of graduates and finally to exclude them altogether.

But is not "Postgraduate" taking an unduly pessimistic view of the future of graduate students in London? Surely the British Postgraduate Medical School at Ducane Road, in whose favour we are, in effect, retiring, can carry on our work with even greater efficiency. They have both a larger hospital and a larger staff—with the advantage that the latter are mostly devoting their whole time to the service of the School. Our annual number of students is rarely more than 250, and it would be very surprising if this relatively small number could not be adequately dealt with at Ducane Road. And, in spite

pathology of the blood he protested against the excessive importance then attached to counts of red corpuscles, to the neglect of more instructive methods of investigation.

The last teaching post held by Buckmaster was that of professor of physiology in the University of Bristol. From his home in Victoria Square, Clifton, he often returned to London to attend meetings of the Physiological Society and renew friendships at the Savile Club, where he was a well-known and much-liked figure. On retirement from the chair at Bristol in 1929 he was elected emeritus professor, and in recent years made long voyages to overseas Dominions, in company with the late Professor William Wright, as travelling examiner for the Primary Fellowship. In recognition of these and many other services to the Royal College of Surgeons he was elected F.R.C.S. in 1934. He had long been a member of the Pathological Society and of the British Medical Association. A man of striking personality, with a vivid mind and an inexhaustible stock of ideas and phrases, his eloquence was almost a by-word among congenial companions. He was a good and faithful friend and a formidable adversary.

Mr. Gordon Gordon-Taylor, F.R.C.S., writes:

A multitudinous host of friends both at home and across the seas will deeply deplore the death of George Buckmaster, for he possessed that genius for friendship which is granted to all too few. A devoted and faithful servant of the Royal College of Surgeons of England, he twice made the journey to Australia and New Zealand when he had already exceeded man's allotted span, and only two years ago he visited India to conduct the physiology part of the Primary Fellowship examination in Calcutta. It was my privilege to be associated with him on the occasion of two visits abroad, and the pilgrimage with him on his second visit towards the Southern Cross strengthened the bond of friendship and augmented one's admiration for this marvellous old man. His contacts had always been many and wide, and I am sure that no more popular visitor has ever been a guest within the hospitable walls of the Melbourne or the Adelaide Clubs in Australia, or in the Wellington or any other of the Clubs in New Zealand where we were so warmly received and welcomed. He was blessed with a wonderful memory; and his brilliant conversation, the interesting anecdote about Victorian or Edwardian times, and the clever story could hold spellbound any audience comprised of any profession or rank. He was liked by all with whom he was associated; he was on respectful yet easy terms with Governors of State or Dominion; he was loved by the officers of the great College of Surgeons of Australasia, by his colleague-examiners as well as by the candidates. He was immensely proud of the Fellowship of the English College of Surgeons, which was conferred on him in the evening of his life. Death has broken an initial link that helped to forge the early friendship between the English College of Surgeons and that of Australasia. "C'est l'homme qui compte"; George Buckmaster, like William Wright who so recently predeceased him, did much to cement that liaison between these two great surgical colleges, sundered by so wide a waste of seas.

Atque in perpetuum, frater, ave atque vale.

A friend writes:

By the death of Professor Buckmaster Bristol has lost one of its most lovable characters. His personality was a unique combination of scholar and man of the world, bookman and clubman, and to those who were fortunate

enough to share his interests he was able to reveal a fascinating charm and an erudition which was never ponderous. He had great power as a raconteur, and his knowledge of that interesting age of men and things termed Victorian enabled him to give an unforgettable picture of that London and those people which are no more. During the first half-century he had met many of the celebrities of his day, he had read much and travelled much, and all his impressions he was able to describe in a way which was as illuminating as it was amusing. I can recall many unforgettable evenings spent in his company when the pleasure was tinged with the regret that in this age of potted music and potted literature the inestimable advantages of conversation as an art and education were gone beyond recall. Professor Buckmaster hid his great love of his fellow creatures and his innate kindness and generous feeling behind a veil of amiable eccentricity, but his inner nature once discerned was an inspiration and a delight. With his passing a link has been snapped with an age which, with all its faults, produced not robots but individuals of whom he was such a notable example.

CHARLES SANDERS, M.B., M.R.C.S.

Late Medical Officer of Health, West Ham

Dr. Charles Sanders died on December 18 last at his residence in Ennerdale Road, Kew Gardens, in his seventy-ninth year. He obtained his medical education at St. Bartholomew's, and after holding posts at the Queen's Hospital, Birmingham, the London and India Docks, and the West Ham Hospital he was appointed medical officer of health to the county borough of West Ham; this became his life's work. He held the appointment for a long term of years with great distinction until he reached the retiring age at 65. A more happy and contented M.O.H. could not be met with, and to his intimates he was ever ready, from his extended experience, to exemplify how this and that difficulty could be surmounted. And to the writer he seemed perhaps even more happy and contented when he quitted official life, emigrated from the East to the West, and settled down in Kew, not omitting to recommend the move to his younger colleagues as it appealed both to himself and his dear wife.

Sanders was a staunch B.M.A. man, having been a member for fifty-five years, elected in 1882; he was president of the Metropolitan Counties Branch in 1923-4, a member of the Council 1923-5, a member of the Public Health Committee 1920-5, of the joint committee on minimum salaries for public appointments 1920-1, and of the superannuation subcommittee. He was also on several occasions a Representative at the A.R.M.; it was here where his quick wit and humour frequently intervened when apparent misunderstandings arose between preventive and curative medicine. Sanders was one who saw no room for misunderstandings; this was probably the keynote of his success.

In 1917-18 Charles Sanders was president of the Society of Medical Officers of Health. The opening words of his presidential address were typical of the man and his modesty. He said: "Disraeli is credited with the remark that when he wanted to read a good novel he wrote one. Would that I could apply this statement to a presidential address, with the eminent statesman's self-reliant assurance of resulting enjoyment, and this not more on my own behalf than yours, for I know how much more pleasant it is to listen to one who wants to speak because he has something to say than to one who has to say something because he wanted to speak." The address dealt with the Prophylaxis of Venereal Disease, and unlike most similar

T. J. Fairbank, A. L. Fawdry, W. Goulstone, J. L. Griffith, E. B. Hacking, S. W. G. Hargrove, F. E. S. Hatfield, H. G. W. Hoare, J. H. S. Hopkins, C. W. Hutt, R. T. Johnson, H. S. Kellett, G. J. G. King, A. P. Kitchin, J. I. H. Laurie, S. A. H. Lesser, R. W. Mason, R. M. Miller, K. S. Mullard, T. L. Oliver, B. G. Parsons-Smith, G. R. C. Peatfield, P. A. T. Phibbs, A. L. Phillips, H. L. Williams, Joyce Worthington.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—Part II: Eleanor B. Schill.

* With distinction.

UNIVERSITY OF EDINBURGH

A graduation ceremonial was held in the Upper Library Hall on December 17, when the following degrees were conferred:

M.D.—†J. A. Chapel, *R. V. Christie, F. L. A. Gacé (*in absentia*), W. Henderson, Helen McD. Hendrie (*née* McDougall) (*in absentia*), *T. B. Johnston (*in absentia*), W. M. McIntyre, W. R. H. Mackay, Jean MacD. MacLennan, W. R. Martine, R. C. M. Pearson, †A. Penman, L. V. Roberts, A. M. Ross, J. O. Westwater.

D.Sc.—T. B. Menon, M.D.
Ph.D. (*Faculty of Medicine*).—A. Haddow, M.D.
M.B., CH.B.—C. A. Anderson, I. L. Briggs, P. E. Brown, A. G. Brownlie, J. A. Cooper, C. F. Coultis-Wood, Millicent C. Dewar, Frances H. Drew, A. El Shaded, A. Farquhar, M. Goldberg, A. Goldblatt, G. H. Hughes, W. Hunter, J. Hurwitz, A. Jeannaco, poulo, R. W. Jones, R. D. Kennedy, R. Kerr, J. W. Leslie, D. P. Macmillan, I. A. G. McQueen, Robina M. Marwick, J. Miedema, J. Milligan, A. D. Mitchell, J. R. Moffat, R. Saffley, R. L. Sanderson, G. Sawh, D. Roworth, J. Runcie, R. Saffley, Stewart, L. Tecluck, W. D. A. Silvera, I. F. Smith, Lesley I. R. B. W. Walker, P. Walton.

DIPLOMA IN PUBLIC HEALTH.—R. P. Jack, K. C. Mathew (*in absentia*).

* Awarded gold medal for thesis. † Commended for thesis.

Obituary

GEORGE A. BUCKMASTER, D.M., F.R.C.S.

Emeritus Professor of Physiology, University of Bristol

We regret to announce that Professor George Alfred Buckmaster, the distinguished physiologist, died at his house in Clifton, Bristol, on December 21, 1937, after some weeks of incapacitating illness.

He was born at Clapham on February 7, 1859, the second son of John Charles Buckmaster of the Science and Art Department, South Kensington. One of his younger brothers was the late Viscount Buckmaster, some time Lord Chancellor of England, and another is Mr. Martin A. Buckmaster, for many years head of the Art Department at Tonbridge School. George Buckmaster was sent to Magdalen College School, Oxford, and entered Magdalen College as a Science Demy at the age of 18. At the University he distinguished himself in the schools, obtaining a first-class in Natural Science in 1881 and the Burdett-Coutts

scholarship in geology in 1882. He studied medicine at St. George's Hospital, and after qualifying in 1883 as M.R.C.S. won a Radcliffe travelling fellowship, which he held for three years. He graduated B.M. in 1885 and D.M. and B.Ch. in 1887, in which year he also took the Oxford D.P.H. During his tenure of the travelling fellowship he worked in physiological laboratories at Leipzig, Kiel, Göttingen, and Berlin. After a period of teaching and research at St. George's he was appointed professor of physiology at the Royal Veterinary College, London, and assistant professor at University College; and for many years served as examiner in physiology for the Primary Fellowship of the Royal College of Surgeons of England and for the medical degrees of the University of London. He was a member of the Leprosy Investigation Commission to India, 1890-1, and made contributions to the *Leprosy Investigation Journal* and to the report of the Commission. He wrote with Mr. J. A. Gardner many papers on the physiology of anaesthesia, blood gases in anaesthesia, rate of elimination of chloroform, and oxygen administration, which appeared in the *Proceedings of the Royal Society* and other journals from 1906 onwards. He also wrote on haemoglobin in the *Journal of Physiology*. Under the title of *The Morphology of Normal and Pathological Blood* Buckmaster published in volume form in 1906 a course of lectures which he had delivered at the Physiological Institute of London University. This book, which was by no means restricted to considerations of morphology, gave a detailed study of some of the latest methods of blood investigation at that time available. It included also an interesting account of an investigation of polycythaemia at high altitudes, which he had conducted in the Alps in conjunction with Dr. Charles Slater and the late Clinton Dent, his former colleagues at St. George's Hospital. Buckmaster devoted special attention to the vexed question of the origin and nature of blood platelets, and in discussing the clinical

There was only one colony for twelve patients suffering from leprosy in this country. As prolonged and close contact with an infected person was necessary for the transmission of this disease the risk of transmission in the conditions normally existing in this country was negligible. A Middlesex patient about whom Mr. Messer asked was now in a London hospital, and she would be admitted to the colony as soon as a bed was available. The local authority in whose area the patient resided was prepared to make a substantial contribution to her maintenance. Steps were being taken by the managers of the colony to raise voluntary funds for an extension of the accommodation.

Typhoid in s.s. "Strathaird"

In reply to Mr. James Hall on December 23, Sir KINGSLEY WOOD said there was an outbreak of typhoid on board the s.s. *Strathaird* on her last homeward voyage in October. It did not appear that any passengers suffering from typhoid were landed at Marseilles. The members of the crew were not inoculated. The names and addresses of the 329 passengers and of the 233 European members of the crew were sent by the London port health authority to the medical officers of health of the districts of destination. Three passengers and two members of the crew gave addresses in Croydon. These were followed up, and were reported by the local authority to have remained in good health. The drinking-water on this ship was adversely reported on when she arrived at Aden. In consequence the water in all the tanks was chlorinated. On arrival at Tilbury instructions were given that all fresh-water tanks should be emptied, cleansed, and cement-washed, and then refilled from the quay hydrant and the water chlorinated. Precautions were taken to the satisfaction of the port health authority to prevent tainted water being pumped into a tank which had been cleansed.

Sir Kingsley Wood further explained on December 23 that notifications of carriers of disease were not included among notifications of disease sent to his department. The statutory obligation to send notice of disease to the medical officer of health of the district concerned related only to persons suffering from the disease. Only such persons were appropriate for admission to an isolation hospital. Persons known to be potential sources of infection but not showing any clinical symptoms of disease should be normally the subject of appropriate precautionary measures at home.

Treatment of Prisoner in Barlinnie Prison

Mr. ELLIOT told Mr. McGovern on December 23 that he had investigated the treatment of a prisoner in Barlinnie Prison, Glasgow, on September 10, 1937, and had that week interviewed the medical superintendent of Gartloch Asylum. After the man had become violent in his cell on September 10 a struggle occurred with warders and he was certified by the assistant medical officer and by another doctor to be of unsound mind. The man, who made no complaint to the governor that he had been ill used, was removed to Gartloch Asylum and was examined there by the assistant medical officer, and on the following day by the medical superintendent. On September 17 the medical superintendent of this asylum certified the man to be of unsound mind. On December 9 the man was fully examined by a deputy commissioner of the General Board of Control, who reported that he was still convalescent from maniacal excitement amounting to certifiable insanity, and should be detained for some time. Since then the medical superintendent had informed Mr. Elliot that he could not at present recommend the liberation of the man, even on probation. Mr. Elliot said that he was satisfied the man's certification on September 10 and his subsequent detention in Gartloch were fully justified by the facts as known to the medical officers concerned.

There was no evidence that he was subjected to force or restraint beyond what was necessary. Consideration of the case had, however, shown the desirability of ensuring that if a prisoner whose sanity was in doubt became violent the medical officer, or in his absence the prison governor, should be present from the earliest possible moment. Directions had

been given accordingly. Where force had to be used against a prisoner and he was bruised or wounded a report would in future be made to the chairman of the visiting committee as well as to the Prisons Department.

Subsequently Mr. McGovern opened a debate on this case, and Mr. MONTAGUE asked for an inquiry. Mr. ELLIOT replied that no further inquiry could now bring out relevant facts.

Mortality of War Pensioners

On the motion for the Christmas adjournment on December 23 Mr. F. O. ROBERTS discussed ex-service men's pensions. He said the death of 51,000 pensioners between 1929 and 1936 showed a mortality rate of 16 per cent. among ex-service men, compared with a rate of 7.6 per cent. for males of similar age among the general population. The time was opportune for a complete survey.

Dr. HADEN GUEST said a review should be undertaken of cases where men had neglected to apply for pensions after the war but had subsequently broken down with maladies such as neurasthenia.

Mr. H. RAMSEOTHAM said there was no evidence of general discount, and he could see no case for an inquiry. It would be impossible to remodel the pensions scheme. The percentage death rate among pensioners was 15.5, compared with 10.5 for the civil population. That was 45 per cent. above the rate for the civilian population for the same age, whereas in the United States the excess was 71 and in South Africa 77. The lower figure in the United Kingdom was attributable to the wonderful health services. He had an open mind about the British Legion inquiry into the question of the prematurely aged ex-service man. He could not now tell the House that there was no such thing as premature ageing by war service.

Fatal Encephalitis following Vaccination.—On December 21 Mr. LEACH asked the Secretary of State for War whether he was aware that Cyril Francis Youngman of Charlton, aged 14, died from encephalitis resulting from vaccination, on December 2, the vaccination having been undergone so that the lad could take up a situation at Woolwich Arsenal: that the Minister of Health, in his recent annual reports, had recommended that children of school age and young adults should not be primarily vaccinated unless in special danger of small-pox, as this operation might cause or activate encephalitis; and whether, in view of this case, he would abolish the regulation requiring certain workers at Woolwich Arsenal to be vaccinated. Mr. HORE-BELISHA said that he had been made aware of the unfortunate circumstances in which this lad died. Such cases were very rare, but he was considering whether the present regulation requiring the vaccination of entrants to the Royal Arsenal should be relaxed. Replying to Mr. Kelly on the same date, Mr. Hore-Belisha said that before an employee was engaged at the Royal Arsenal he was required to be vaccinated. As the vaccination was done by his own private arrangement, he had no information whether any case had resulted in the death of the man vaccinated.

Investigation into Prevention of Silicosis.—On December 21 EARL WINTERTON informed Mr. J. Griffiths that the progress of the investigation conducted by a group of scientists at the McIntyre Mine, Ontario, Canada, into the possibility of the prevention of silicosis by the admixture of metallic aluminium with silica dust was being followed with interest by the special committee advising the Medical Research Council in this subject. Some experiments on similar lines had already been initiated in this country.

Appointment of Salaried Midwives.—On December 21 Mr. BERNAYS, replying to Sir Robert Young, said that the number of salaried midwives included in the proposals of local authorities under the Midwives Act, 1936, was approximately 7,550. It was safe to assume that a large majority of the midwives had already been appointed. Returns showing the exact numbers appointed by the end of this year would be available next February. The Minister of Health was not aware that any serious difficulty had been experienced in any part of the country in securing the requisite number of midwives.

addresses was intended to open a discussion. The subject was much in the air at that time, and the meeting was a notable one in the history of the Society; Sir James Crichton-Browne, Sir Frederick W. Mott, and Miss Ettie Rout among others took part. One of his first presidential duties was to head a deputation to the President of the Local Government Board (Mr. Hayes Fisher) in favour of better co-ordination of the public health services by the appointment of a Minister of Health.

There are many who will greatly miss the cheery word and countenance of Charles Sanders, who for so long had been a stalwart in the Public Health Service.

E. H. S.

Dr. CECIL ERNEST JONES-PHILLIPSON, who died on November 13 at Capetown, aged 67, was a student of St. Bartholomew's Hospital, and took the English Conjoint diplomas in 1896, obtaining the F.R.C.S.Ed. and the M.D.Brux. in 1903. He settled in South Africa soon after qualification, and practised at Port Alfred from 1906 to 1916. He then went on active service to France with a commission in the R.A.M.C., and served as an aural specialist to the British Expeditionary Force. After the armistice he returned to South Africa and started practice as an ear, nose, and throat specialist. Dr. Jones-Phillipson joined the British Medical Association in 1898. He was president of the Cape of Good Hope (Eastern Province) Branch in 1906 and president of the Cape Western Branch of the Medical Association of South Africa (B.M.A.) in 1924-5. He published several papers on oto-rhino-laryngological subjects in the *South African Medical Journal*.

We regret to announce the death of Dr. JAMES MCKAY of Coatbridge on December 9 after a short illness. A native of Dumbarton, Dr. McKay graduated M.B., C.M. in 1892 and M.D. in 1911 at Glasgow University. He practised in Coatbridge for about forty years as a general practitioner, was an active member on the staff of the Alexander Hospital, Coatbridge, and retained that connexion until a few years ago. For the past thirty-six years he had been a member of the British Medical Association. Dr. McKay was a man of outstanding character, quiet and unassuming, who devoted his whole life to the interests of his patients and profession. He was held in high esteem by his professional colleagues, and his death is deeply regretted by a wide circle of friends.

On October 30, 1937, aged 63, there passed away in the person of Mr. HARRY HOLMES, B.A., M.B., B.Ch., one of the best friends of the voluntary hospital system of Merseyside. Springing from sturdy yeoman stock in Lincolnshire, he had all the good qualities of the typical Englishman, sharing also the reticence and self-effacement. From St. John's College, Cambridge, he entered St. Bartholomew's Hospital, and graduated in medicine in 1896, and early in his career became associated with the Wigan Infirmary as junior and then as house-surgeon. Appointed in 1904 to the honorary staff of the Eye and Ear Infirmary, Myrtle Street, Liverpool, he spent the best of his life, health, and energy in unostentatious work in Wigan as ophthalmic and aural surgeon. Mr. Holmes (writes C. A. H.) was a brilliant chess player who held many championships; he nevertheless put his duty to his work first; and, indeed, there were few who maintained a more consistent level of all-round good results in his clinical work year in, year out. Joining the North of England Ophthalmological Society as a foundation member in 1914, he served on its council in 1925, and he had been a member of the British Medical Association for the past twenty-seven years. His skill and ability often went unnoticed, so modestly was it tendered; but it was on the point of character that he will be best remembered by his medical friends as one "more skilled to raise the wretched than to rise."

Medical Notes in Parliament

In the House of Lords, on December 22, a Royal Commission, consisting of the Lord Chancellor, Viscount Dawson of Penn, and Lord Stanmore, signified the Royal assent to the Air Raid Precautions Act. On the same day the Unemployment Insurance Bill, which has passed the House of Commons, was read a first time, the Criminal Procedure (Scotland) Bill was presented by Mr. Elliot and read a first time, and the Dogs Act (1871) Amendment Bill, which is introduced by Sir Robert Gower, a second time. The Criminal Procedure Bill is to amend the law of Scotland relating to criminal procedure and to incest and to fatal accident inquiries.

A motion was adopted by the House of Commons on December 22 which called for further measures, including more strict and uniform administration of the Shops Acts, to raise the conditions of employment in the distributive trades.

Mr. Elliot announced on December 22 that it had been decided to appoint a representative committee to review the whole field of public health law and local government law in Scotland and to prepare the necessary measures for its revision and consolidation. Sir John Jeffrey had been appointed chairman of the committee.

The House of Lords adjourned on December 22 till February 1, and the House of Commons on December 22 to the same date. Provision was made for an earlier summoning of Parliament in the event of urgent need. On February 1 the House of Commons will take the committee stage of the Population (Statistics) Bill and will further consider the Blind Persons Bill.

A motion to set up the projected committee on road accidents will be among the earliest business of the House of Lords after its reassembly.

Inquiry into Tuberculosis Services in Wales

Sir KINGSLEY WOOD told Mr. Jenkins, on December 22, that the report of the committee of inquiry into the anti-tuberculosis services in Wales and Monmouthshire was not completed. Bodies who wished to give evidence before the committee were asked to complete and submit a written summary of their evidence before the end of the year. The committee hoped to hold a public sitting in Cardiff early in the New Year. Further sittings would be necessary. He would consider publication of the report as soon as he received it.

Ophthalmic Benefit

Sir KINGSLEY WOOD announced on December 23 that ophthalmic benefit was included among the additional benefits available to the members of 730 approved societies and 4,769 branches, with a total membership of 11,300,000. Members of these societies became entitled to the benefit after a waiting period of 2½ years on average, but after the completion of the waiting period the benefit was available to all classes of members. Legislation to make ophthalmic benefit available to all members of all approved societies could not at present be contemplated.

Leprosy Incidence and Treatment

Sir KINGSLEY WOOD, in a reply to Mr. Messer on December 23, said cases of leprosy were not required to be reported to his Department, but he had information of thirty-eight cases in this country. In only four over a long period of years was it considered that the infection was incurred in this country. In each of these there was a history of prolonged and intimate contact with a person who contracted the disease abroad.

EPIDEMIOLOGICAL NOTES

Typhoid Fever.—The number of cases notified in the Croydon epidemic at the time of going to press was 289, with 31 deaths. It will be observed that for the week ended December 18 there were 24 notifications of enteric fever; the "expected" figure based on the median value for the last nine years was 27, the figure which was returned for the corresponding week last year.

Measles.—Measles is not generally notifiable in the British Isles. In some areas in which notification is in force only the first case in a household is required to be notified unless a period of two months intervenes. Reports of absences from school on account of measles only partially fill the gap, as measles is essentially a disease of children under school age in large centres of population. In Scotland and Northern Ireland notifications suggest that an epidemic is in progress at the present time. Measles is expected in London this year according to the law of biennial periodicity in densely populated areas, and already some boroughs, notably Fulham, in London have reported large numbers of cases. The weekly number of deaths from measles provides a fairly reliable guide to the prevalence of the disease; it is evident that the figures for the deaths from measles in our table reflect the prevalence of the disease two to three weeks previously.

Medical News

A meeting of the West London Medico-Chirurgical Society will be held at the De Vere Hotel, Kensington Road, W., on Friday, January 7, at 7.45 p.m., when there will be a discussion on "Sterility," to be opened by Messrs. Eardley Holland, Kenneth Walker, V. B. Green-Armytage, and F. J. McCann.

A meeting of the Society for the Study of Inebriety will be held at 11, Chandos Street, W., on Tuesday, January 11, at 4 p.m., when papers will be read by Dr. W. Norwood East on "Some Official Contacts with Addiction (National)" and by Major W. H. Coles on "Some Official Contacts with Addiction (International)." A discussion will follow.

A discussion on "Recent Advances in Methods of Bed-bug Disinfection" will take place at the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W., on Tuesday, January 11, at 5.30 p.m. Mr. S. A. Ashmore and Dr. B. T. J. Glover will open the discussion, and a demonstration of the methods described will be given by Dr. J. Macmillan.

The tenth annual Congress of the Egyptian Medical Association will be held at Baghdad from February 9 to 13, when the following subjects among others will be discussed: surgery of the liver and gall-bladder, malaria, cholera, and undulant fever. The subscription is one Egyptian pound. Further information can be obtained from the General Secretary, Kasr-el-Aini, Post Office, Cairo.

At the annual meeting of the Save the Children Fund, whose offices are at 20, Gordon Square, W.C.1, Lord Noel-Buxton stated that the basis of its work at home and abroad was the Declaration of the Rights of the Child (Declaration of Geneva), to which the Prime Minister had recently given his approval. Sir Francis Fremantle said that the Fund in its work in this country was helping to protect from the worst evils the sensitive minds of children and the bodies they controlled. It was also helping to fill a gap in the public health services for "toddlers," aged 2 to 5, by the provision of nursery schools, particularly in the special areas. Dame Rachel Crowley commended the work of the Fund for the victims of the war in China. Lord Snell, chairman of the London County Council, said that one of the Fund's principal claims to support was that in setting out to help a child it took into consideration neither his race nor the religious convictions of his parents.

At a meeting of the Governing Body of University College Hospital on December 16 it was announced that Sir Herbert Samuelson, the former chairman and treasurer of the hospital, had made a gift of £10,000 towards reduction of the debt on the building fund. The debt, amounting to £200,000, was incurred as the result of the building of the private patients' wing and sisters' home, and extensions to the ante-natal and child welfare departments.

The issue of the *South African Medical Journal*, the organ of the Medical Association of South Africa (B.M.A.), for November 27, 1937, is a special tuberculosis number, with an account by Sir Edward Thornton of the policy of the Union Public Health Department for dealing with tuberculosis in South Africa. Other contributors are Drs. D. P. Marais, Strafford Hewitt, P. Allan, J. A. Macfadyen, W. H. Horne, and A. Bloom. Surgical tuberculosis is deferred to a later occasion, the present articles dealing solely with the medical side of the problem.

The issue of the *Bulletin de l'Office International d'Hygiène Publique* for October, 1937, is devoted to plague in the French colonies, India, and Tunisia; infantile paralysis in the United States, Italy, New Zealand, Sweden, and Yugoslavia; and cerebrospinal fever in the United States and Turkey.

The issue of *Paris médical* for December 4 is devoted to therapeutics; that of the *Journal de Médecine de Lyon* for November 20 to legal and social medicine; and that of *Le Bulletin Médical* for November 27 to paediatrics.

Mr. E. W. Meyerstein has given to St. Mary's Hospital £32,576 for the purpose of acquiring the freehold of a site of 10,500 square feet adjoining the hospital in Praed Street, Paddington, thus providing land needed for the extension of the hospital. In appreciation of this and his earlier gift of the Meyerstein Dental Research Laboratory at St. Mary's, Mr. Meyerstein has been elected a vice-president of the hospital.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES are
EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology
Westcent, London.

SECRETARY, Medisecra Westcent, London.
The address of the B.M.A. Scottish Office is 7, Drumsheugh Gardens, Edinburgh (telegrams: Associate, Edinburgh; telephone: 24361 Edinburgh), and of the Office of the Irish Free State Medical Union (I.M.A. and B.M.A.), 18, Kildare Street, Dublin (telegrams: Bacillus, Dublin; telephone 62550 Dublin).

QUERIES AND ANSWERS

Frumenty

Dr. ARCH. R. MILLER (Glasgow) writes: In the *Journal* of December 18 Dr. Josiah Oldfield urges the use of "frumenty" for the prevention of constipation in "normal human beings." Would it be convenient for Dr. Oldfield to supply the recipe for "frumenty" to one of the conquerors who is not above learning if possible from the conquered?

* "Frumenty" and "furmety" are alternative names for a sort of porridge made with hulled wheat boiled in

EPIDEMIOLOGY AND VITAL STATISTICS

No. 50

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 18, 1937.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Irish Free State. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 125 great towns (i) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns (ii) in the Irish Free State. (e) The 10 principal towns (iii) in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1937					1936 (Corresponding Week)					1928-36 (Median Value Corresponding Weeks)

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

1

Non-tropical Sprue

H. STALDER (*Schweiz. med. Wschr.*, November 13, 1937, p. 1091) describes briefly the symptomatology of non-tropical sprue and reports two personal cases. He believes that non-tropical sprue is probably a secondary B. avitaminosis. The administration of vitamin B₂, which is a compound of flavine and phosphoric acid present in yeast, has brought about a cure in one of the cases after all other therapy had failed. The blood picture was improved at the same time. The necessary dose of vitamin B₂ varies according to the gravity of the case. The favourable effect of campolon on non-tropical sprue is probably due to the presence of small quantities of flavine-phosphoric acid in it. These small quantities may, however, be insufficient for certain grave cases of sprue. In such patients large doses of yeast may prove effective. The effect of the hormone of the adrenal cortex in sprue is uncertain, although the weakness, hypotension, anaemia, hypoglycaemia, and pigmentation certainly indicate an adrenal insufficiency.

2

Diphtheria Immunization

D. T. FRASER and K. C. HALPERN (*J. Immunol.*, October, 1937, p. 323) report an investigation in children of the antitoxic response to diphtheria toxoid, and the persistence of the antitoxin in the blood during the three years following inoculation. In all 244 children were studied in various groups. Of 108 children tested three months after a course of three injections of toxoid, 107 had developed such a concentration of antitoxin as would render them Schick-negative, and their degree of immunity as judged from antitoxin concentration was as good as that of 175 "naturally immune" women. The authors regard these results at three months as a standard of response against which other responses may be measured. After three months there was a gradual fall in the mean antitoxin concentration in the blood of the groups of children studied, so that after twelve months the mean concentration had fallen to 50 per cent., and in three years to 34 per cent., of the mean value at three months. On the other hand, in thirty of thirty-three "naturally immune" adults the antitoxin concentration did not change in four to six years, while in two of them it increased. It appears, therefore, that naturally acquired immunity is more lasting than that artificially acquired. During the three years' period of the observations diphtheria was not prevalent in the district, so that the effects of secondary stimuli were absent. From a comparison of the antitoxic responses evoked by different toxoids with the standard results obtained three months after three doses of toxoid, the authors suggest a method of assessing the antigenic value of toxoids.

3

School Epidemics of Tuberculosis

C. WISHMAN (*Tidsskr. norske Laegeforen.*, September 1, 1937, p. 885) justifies the Norwegian law of 1935 concerning the medical examination of school teachers by an account of a small epidemic of tuberculosis among adolescents, their infection being traced to a tuberculous school master who had already undergone sanatorium treatment. In February, 1936, he developed "influenza," which required medical treatment but did not lead to his discharge as a teacher. His class consisted of nine boys and fifteen girls between the ages of 14 and 18. Late in April of the same year one of the scholars developed erythema nodosum. Four new cases of erythema nodosum occurred in May and June, and three other scholars

developed high fever without physical signs. Mantoux's subcutaneous tuberculin test was positive in twenty of the twenty-four—a remarkably high proportion of positive reactions considering that there was very little tuberculosis in the district, and only two of the scholars were known to have been exposed to infection before joining the particular class in question. These two scholars remained perfectly well. All twenty-four scholars save one not thus examined showed an abnormally high sedimentation rate, but in those who were in other respects symptom-free the rate returned to normal after some time. Apart from the seven scholars who developed erythema nodosum or high and protracted fever, there were seven others with a sub-febrile temperature, general malaise, and a definitely abnormal sedimentation rate. The remaining ten scholars, six of whom were tuberculin-positive, remained comparatively well. But all twenty-four showed hilar shadows which, in some cases, were associated with lung shadows.

4 A. SASSE (*Nord. med. Tidskr.*, October 9, 1937, p. 1664) gives an account of an epidemic of tuberculosis in a school in Sweden. In this school in 1934 tuberculin tests showed ten of the forty-four older children and only one of the fourteen younger children to be positive reactors. When the tuberculin testing was repeated in the autumn of 1935, little change was found in the older children, ten out of thirty-five proving to be positive reactors. But among fifteen younger children there were now five positive reactors. In December of the same year the woman teacher in charge of the younger children was found to be suffering from infectious pulmonary tuberculosis. Though she ceased to teach and the school was disinfected, tuberculin testing of the children in the spring of 1936 showed that all the younger children had become positive reactors, whereas there was no change in this respect in the older class. Radiological changes were demonstrable in all the younger children, the rate of sedimentation was accelerated in most cases, several had been ailing in the winter, but the symptoms were for the most part slight or limited to catarrhal phenomena. The investigation was now extended to the families of all the school children who were positive reactors, and as many as fifteen children were given sanatorium treatment as a prophylactic measure. The lessons of this epidemic are, in the author's opinion, that school teachers should be medically examined before they are appointed and at any time when they are ailing, and that successive tuberculin surveys of school children should be carried out systematically. For if the State compels parents to send their children to school, the parents are entitled to expect the State to take the necessary medical precautions.

Surgery

5

Pyogenic Pelvic Osteomyelitis

J. KULOWSKI (*Arch. Surg.*, Chicago, September, 1937, p. 571) points out that, although pyogenic osteomyelitis of the pelvis is a relatively common disease, the primary lesion is often overlooked or subordinated to the predominant simulative signs and symptoms or to the more extensive secondary parosteal purulent infiltrations. In a series of 1,496 cases of pyogenic osteomyelitis there were ninety, or 6 per cent., in which the focus of infection was in the pelvis. The ratio of males to females in the group was approximately 2 to 1. Pelvic osteomyelitis is primarily a disease of the growing period, and in the series about 60 per cent. of cases occurred in the second decade. Boils were the most common localized infection of the skin. Antecedent trauma was recorded in thirty-five instances, and in most of these the onset of symptoms

milk and seasoned with cinnamon, sugar, etc., which was popular as an English dish in former times. The name is derived from *frumentum*, Latin for corn. Dr. Lionel Picton or Dr. Oldfield will no doubt be able and willing to give details of how to prepare frumenty. We have had inquiries from several readers.

Painful Tongue

Dr. R. D. MOYLE (Eastbourne) writes in reply to "Worried" (*Journal*, December 18, p. 1259): In the past month I have seen two patients (females) who complained of this "burning pins and needles" affecting the tongue. In one case nothing abnormal was seen, while in the other there was a mild erythema over the anterior part of the tongue. Microscopical examination of a scraping in this second case showed a monilia-like fungus, but this is not uncommon in the mouth. A pigment containing liq. arsenicalis, tinct. ipecacuanha, and glycerine, one drachm of each to an ounce of aqua menth. pip., well rubbed in with cotton-wool on a match-stick three times daily, has been successful in clearing up the complaint.

Incapacitating Diarrhoea

Dr. VICTORIA H. KING (Birmingham) writes in reply to "Emdee" (*Journal*, December 11, p. 1206): The morning diarrhoea suggests to me pancreatic deficiency. If so, it would be relieved by enteric-coated pancreatin tablets. I have found Parke, Davis's efficacious in a similar case.

Dr. W. M. M. JACKSON (Folkestone) also writes: I would suggest to "Emdee" that he should stop smoking and take twice daily in a little water 30 minims of mist. bismuth. & pepsin. If this is ineffective an analysis of the faeces might be of value.

Income Tax

Sale of Book Debts

"PERPLEXED" bought a practice as from January 1, 1936, and sold it as from December 31, 1936. The cash receipts were £2,000 and the outstanding debts, amounting to £1,000, were sold for £600. What should be regarded as the amount of the gross receipts of the practice for 1936?

The answer is £3,000 less such an amount as can be deducted from the £1,000 book debts for anticipated losses by bad and doubtful debts. Clearly there would be some loss, but the allowance is not necessarily as much as £400—the difference between the gross amount and the sum received on the lump sum sale. That form of realization has special features—for example, anticipation in point of time and saving of cost of collection—for which no allowance can be claimed. The correct basis of calculation would be to draw up a schedule of the debts at December 31, 1936, and value each one on the question of recoverability; the aggregate of the differences would be the amount by which the £3,000 can be reduced to represent the gross receipts.

LETTERS, NOTES, ETC.

Subcutaneous Emphysema during Labour

Mr. VAUGHAN PENDRED, F.R.C.S. (Tilford, Surrey), writes: In connexion with the case reported by Dr. F. H. Nussbaum in the *Journal* of December 11 (p. 1169), I should like to record that of a relative of mine, aged 25. For the last three months of gestation she had been severely dieted for albuminuria. The baby, her first, was born normally, and the doctor in attendance called me up to report hours later the patient's husband called me up to report that there was a swelling of his wife's left face and neck. On my suggestion he palpated it and found that the area "crackled" when he pressed it. A consultant was called, who found that the emphysema affected the left arm and a considerable part of the left side of the body. In a few days the air had been absorbed, the albuminuria disappeared, and the patient returned to her usual excellent health; two years later a second healthy son was born. Some years before the first pregnancy a mass of tuberculous glands was dissected from the right side of her neck. We thought that a small tuberculous infiltration had occurred in the left lung, sealing the overlying pleura, and had ruptured into the subcutaneous tissues during the straining of delivery.

Dr. P. PHILLIPS (Bristol), in connexion with Dr. Nussbaum's memorandum, writes: This unusual happening is certainly one of the rarer accidents of labour, for in over 3,000 maternity cases delivered in the Southmead Hospital under my supervision, between 1923 and 1932, it was not observed in a single case. However, from 1932 to 1936 five such cases have been recorded out of 3,650 deliveries. All the patients were young primiparae, aged 18, 18, 19, 21, and 21 years, and delivery was normal. Their efforts during the second stage of labour might be described as unusually vigorous, and in each case restlessness was noted. In four of the patients emphysema did not develop until after the completion of labour, while the fifth complained of a sudden pain in the right side of the chest and face about forty minutes before the actual delivery. This was followed by rapid swelling of the right side of the face and neck, the right eyelid becoming swollen first; delivery was taking place in the left lateral position. About twelve hours later the emphysema had extended down the neck and chest to the level of the breasts, but still remained more marked on the right side. All five made uninterrupted recoveries, though the pulse rate usually remained rapid at about 90 to 100 for some seven days. I have photographs of one case and a short cinematographic record of the day-to-day recovery in another. With regard to the aetiology of this condition, all my cases were examined for carious teeth or possible abnormal communications between the mouth and nasal sinuses; none was found. In no case was there a history of chest trouble or tuberculosis; x-ray examinations of the chest were made within twenty-four hours of the onset of the emphysema, but no evidence of pneumothorax was found. Consequently it seems unlikely that the condition resulted from rupture of air vesicles in the lung, unless at some point very near to its root. In the straining of labour it would appear that the glottis must be closed during the act of bearing down. Consequently one would imagine that the escape of air most probably takes place at some point between the root of the lung and the glottis, whence it tracks up through the mediastinum and usually appears first on the face. In my opinion a tenable theory is that in a few rare cases there is some anatomical weakness or deficiency in the structure of the trachea or bronchi. Straining produces a slit-like rupture in the wall which, acting as a valve, allows the intermittent escape of small quantities of air into the mediastinum. This would also account for the cases in which emphysema does not appear until labour is complete. Obviously such a theory is difficult of proof, but with continuous observation and interest a satisfactory explanation may be found. The first case I witnessed caused me considerable alarm, but it is some consolation to know that the prognosis is invariably good and the swelling disappears in a few days without treatment.

Herpes and Varicella

Dr. I. H. LLOYD-WILLIAMS (Southport) writes: The relationship between herpes zoster and varicella is one that is ventilated in the *Journal* from time to time but apparently without any definite conclusions being arrived at, except that they are both virus diseases. The following notes of cases are forwarded as a further small contribution to the problem. I have had lately under my care a man of 65 who on November 10 developed herpes zoster of the second and third left sacral nerves, the eruption affecting the back of the thigh and side of the scrotum and penis. On November 25 his grandson, who lives in the same house, developed a typical varicella. These dates agree with the incubation period of chicken-pox. I met, about ten years ago, a somewhat similar coincidence, where the child had varicella and the mother, who had nursed her, developed herpes. These cases, and similar ones which have been noted in the *Journal* before, suggest that the disease which is developed by the transmitted virus depends on the soil as to whether the infection becomes general or local. It is unusual for a second attack to occur or for the same patient to have both diseases. In view of the latter it is perhaps worth recording that as a child I had chicken-pox, and about ten years later at school I had herpes zoster. Accepting the theory that it is the same virus causing both diseases, one wonders whether in my own case the immunity developed from the first attack was not quite complete and that with a second infection (source unknown) only a local manifestation was produced. An alternative theory occurs to me is that there may be different strains of the same virus causing the two diseases.

larly, the month of pregnancy of the donor being the same as that of the actual mother), but 10 to 50 mouse units per kilogramme of body weight of follicular hormone may be used. Thyroxine is called for not only in the cretin, but also in the child with partial thyroid insufficiency, shown by some or all of the following symptoms: slight retardation of mental and physical growth; oedematous, dry skin; swollen tongue; broad nasal summit; and severe constipation. Cryptorchism, usually combined with infantilism, eunuchoidism, or dystrophia adiposogenitalis, should always be treated primarily by anterior pituitary hormones, those derived from whole gland being preferable to those from pregnancy urine. Several months' oral administration is required. Other fields for hormone therapy in childhood are found (1) in vulvo-vaginitis, in which folliculin medication induces cornification and thickening of the vaginal epithelium, and (2) in toxic diphtheria, in which adrenal cortical hormone, given together with vitamin C, is said to have saved desperate cases. The swelling of the breasts; growth of pubic hair, and even menstruation which have followed sex hormone treatment in children have regressed after its suspension, and injurious effects have not been reported.

10

Gonorrhoeal Arthritis

E. WANDERER (*Wien. klin. Wschr.*, September 17, 1937, p. 1300) divides gonorrhoeal arthritis into four types: (1) with serous inflammation of the joint; (2) with serofibrinous inflammation; (3) with purulent inflammation; and (4) gonorrhoeal articular cellulitis. The inflammation may be either monarticular or polyarticular. Of fifty-four cases of gonorrhoeal arthritis forty-one were males (76 per cent.), twelve females (22 per cent.), and one a child (2 per cent.). In 43 per cent. of cases the inflammation was monarticular and in 57 per cent. polyarticular. The knee-joint was involved in thirty-three cases, the ankle in nineteen cases, the wrist in twelve cases, the toes and fingers in twelve cases, the shoulder-joint in eight cases, and the sterno-clavicular joint in one case. The articular inflammation occurred usually at the end of the third week. The author advocates non-specific local therapy in the form of compresses, Bier's hyperaemia, hot-air baths, etc., specific therapy such as injections of trypaflavine or vaccines, and specific local treatment.

Ophthalmology

11

Operation for Adherent Leucoma

A. BUSACCA (*Klin. Mbl. Augenheilk.*, October, 1937, p. 472) describes the first stages of an operation for adherent leucoma in which post-corneal adhesions make keratoplasty impossible. In the first stage a very thin ivory shell corresponding to the surface of a lens of 40 D was implanted through a limbic external incision after freeing of the irido-corneal angle. After five weeks the eye condition settled down, and the periphery of the shell was visible by the slit-lamp three weeks later. In the second operation, five months after the first, the cornea from an enucleated eye was transplanted: it regained its transparency in eight weeks. In a third stage Busacca proposes to remove the ivory, together with the cicatricial tissue and the lens.

12

Allergic Oedema

L. WEEKERS (*Arch. Ophthalm.*, Paris, September, 1937, p. 769) describes a paroxysmal type of allergic oedema affecting the globe and giving rise to oedema of the cornea with hypercholesterolaemia. It can be unilateral and associated with a similar affection of the iris and a

punctate keratitis; the aqueous and vitreous may contain fine opacities, and sometimes the tension may be raised. The attacks correspond with violent headaches not to be confounded with migraine. The intervals between attacks vary and, in the worst forms, loss of the eye results. The condition in most cases has a definite connexion with digestion and with angioneurotic oedema. Dieting, desensitization, protein therapy, histamine ionization, and the use of calcium, magnesium, sodium hyposulphate, and adrenaline are of great value. The syndrome is related to alterations in the sympathetic system and the permeability of the capillaries.

13

Problems in Refraction

A. DEH. PRANGEN (*Arch. Ophthalm.*, Chicago, September, 1937, p. 432) insists that refraction cannot be successfully practised without taking into consideration the inalienable relationships between the ophthalmic, general medical, and neurological aspects of the case. There are definite differences in the visual capability and reactions of the emmetropic, the myopic, the hypermetropic, and the astigmatic eye, nor can the same performance be expected from each one. The measurement and correction of aniseikonia is still in the experimental stage, and not yet a matter of general clinical application. The accommodation should be estimated and a watch kept for spasm of the ciliary muscle; cycloplegics are essential. The author gives rules to be observed in the treatment of muscular imbalance, in the correction of astigmatism, and in finding the spherical equivalent of an astigmatic correction. He describes fully the unequal prismatic effect which may be due to using an eccentric part of a lens for reading, and the difference in power caused by alteration in the distances of lenses from the cornea.

14

Tonometry

J. S. FRIEDENWALD (*Amer. J. Ophthalm.*, October, 1937, p. 985) points out the errors which may affect readings taken with a Schiötz tonometer. For the same intraocular pressure, the greater the rigidity of the globe the higher the reading. An empirical formula evolved to correct this variation, and calculations of the intraocular pressure with each weight, led to the formation of a nomogram from which the coefficient of rigidity of an eye can be calculated; by allowing for the indentation of the cornea caused by the foot-plate the true intraocular pressure may be computed. The coefficient of rigidity in a normal eye is inversely proportional to the volume and is affected by the refraction, the corneal curvature, age, inflammation, congestion, and the use of vasodilators and vasoconstrictors.

15

Divergent Strabismus

E. E. CASS (*Brit. J. Ophthalm.*, October, 1937, p. 538) adopts Duane's classification of convergence insufficiency and divergence excess with the addition of "consecutive divergence" for cases which, previously convergent, have had no operation. She records many cases with detailed notes on aetiological factors, refraction, and binocular vision. Except in myopes, glasses are of little use, hypermetropes and those with consecutive divergence being best left uncorrected. Occlusion should be as complete as possible where amblyopia is present, and orthoptic treatment is most successful in cases of divergence excess and consecutive divergence. After promoting diplopia and improving the fusion power, convergence is encouraged finally with the use of prisms. Cases with false correspondence have a bad prognosis. Training should be given before and after operation when this is indicated. The external rectus should be recessed and the internal advanced, but the results of operation are not as favourable as in convergent squint.

followed direct or indirect injury. Pelvic osteomyelitis may be a direct or a haematogenous infection; there were twenty-three cases of the former and sixty-seven of the latter type of infection. Staphylococci were recovered in the majority of instances. The most striking pathological feature is the relatively "dry" bony reaction, while extensive suppuration in the soft tissues is characteristic. Suppuration was observed in over 83 per cent. of cases. Radiography is essential for diagnosis and prognosis, particularly in the subacute and chronic stages of the disease. The entire pelvis and the lumbar portion of the spine must be examined, and lateral views of the iliac bones and hips are of value. The essential changes shown are osteoporosis, sequestration, and bone production. The injection of a sinus with a radiopaque substance is strongly urged as an aid to diagnosis. Treatment at the onset must be non-operative until localization in the soft tissue has taken place. Simple incision and drainage is then usually sufficient until more definite pathological skeletal changes are manifest. Wide excision of the affected bone is the ideal to be aimed at, but complications may render this difficult. Eighteen cases are described in which operation following the technique of Orr was carried out in nearly every instance.

6 Carcinoma of the Lung

P. LIVRAGA (*Arch. ital. Chir.*, 1937, 47, 1, 63) gives radiographs and clinical descriptions of twenty-two cases, from Sauerbruch's clinic, in which exploratory thoracotomy was done to establish the diagnosis between cancer of the lung on the one hand, and abscess, gangrene, bronchiectasis, tuberculous cavitation, interlobar empyema, infarction, syphilis, or hydatid cyst on the other. He notes that some two-thirds of the cases were of hilar growths, and that although early bronchial carcinomata are removable by the bronchoscopic route, they commonly first come to observation when mediastinal metastases have made them inoperable. In biopsy during a thoracotomy operation the tissue should be taken as far as possible from the parietes, for there it is usual to find signs of secondary atelectasis or pneumonic infiltration without evidence of the neoplasm which causes them. Abscess formation is a frequent complication of pulmonary neoplasm, and cancer may supervene in a tuberculous or bronchiectatic cavity. Tomography facilitates diagnosis. Detection of numerous soot granules in the pus from a pulmonary abscess is said to exclude a neoplastic source. Intercostal thoracotomy usually suffices for growths in the lower thorax, but near the apex costal resections are required; ether anaesthesia is essential for the intrathoracic part of the operation. For lobar or total pneumectomy the two- or three-stage operation is generally preferable; the one-stage operation with opening of the pleura is unsuitable for cases with secondary infection. Among palliative operations, which in Livraga's experience may be of great help, are: (1) wide costal resection, possibly combined with phrenic resection, for late pleural syndromes and for dyspnoea accompanying tracheal distortion or displacement; (2) antero-superior longitudinal mediastinotomy for the mediastinal syndrome of facial and brachial oedema and cyanosis, with which may be associated recurrent laryngeal and phrenic paralyses and signs of stimulation or paresis of the cervical sympathetic; (3) section of the posterior spinal roots; and (4) chordotomy. Gowers's tracts being divided within the spinal cord. Two antero-superior longitudinal mediastinotomies which took place in Stropeni's clinic are described.

7 Fracture of the Base of the Skull

A. FEHR and E. J. MEIR (*Beitr. klin. Chir.*, 1937, 166, 2, 177) review 417 cases of fracture of the base of the skull (gunshot injuries excluded) treated conservatively by at least three to four weeks' rest, ice applications, hexamine, lumbar puncture, and daily intravenous injections of 40 to 100 c.c.m. of 20 to 40 per cent. dextrose

solution, to which hexamine is sometimes added. Only thirty-two cases needed operation to relieve increasing intracranial tension; the mortality in these cases was 81 per cent., compared with 72 per cent. in 385 cases not operated on. It has been suggested that fractures of the base of the skull should be treated by otorhinologists, of the vault by general surgeons; but Fehr and Meir point out that in the large majority of cases (four-fifths according to Schönbauer and Brunner) both base and vault are broken. The review does not support the suggestion that the mortality would be diminished by early prophylactic operation on fractures of either anterior or middle fossa. Operation is called for, however, in the former case, when intracranial extension of a demonstrable infection of the accessory nasal cavities is to be feared. Meningitis more commonly follows anterior fossa fractures, but has recently been found less frequent than has been believed—for example, 4.8 per cent. in the present series. In fractures of the middle fossa it is important, although not always easy, to find out if the fracture is longitudinal, or transverse with opening of the labyrinth: the latter fracture, although much less common, carries a greater danger of meningitis. Clinically, the transverse fracture is associated with deafness, insensitiveness to heat, permanent facial palsy in half the cases, and absence of bleeding from the ear or rupture of the tympanum; the longitudinal fracture with aural discharge of blood and liquor, fracture of the bony canal, rupture of the drum, a moderate degree of middle-ear deafness, sensory chorda tympani changes, and sometimes a transitory facial paralysis. The discharge of cerebrospinal fluid in Fehr and Meir's experience is not a specially dangerous sign. In transverse temporal fractures operation must be considered, especially if a purulent middle-ear infection is present or if signs of incipient meningitis are noted; patients having these fractures are specially prone, owing to the fibrous nature of the union, to late meningitis, and should therefore remain under observation.

8 Pseudarthrosis of the Shoulder

M. M. KASAKOV (*Vestnik Chirurгии*, 1937, 52, 138, 200) reports thirteen cases of pseudarthrosis of the shoulder treated with bone grafts taken from the patient's tibia. The main technical points of the operation are: the resection of the false joint together with the cicatricial tissues; the firm fixation of the ends of the graft in the medullary canal of the humerus; and the thorough enveloping of the graft with muscular tissue. Following the operation the limb is fixed in an abduction splint for two and a half to three months. In severe cases of pseudarthrosis the author uses two bone grafts, one intramedullary, the other juxtadiaphysial. The additional support supplied by the second graft together with the lengthened period of fixation after the operation secures the necessary strength of the limb. In cases in which the radial nerve is either injured or compressed the author recommends freeing the nerve during the main operation and separating it from the bone graft by a layer of muscle.

Therapeutics

9 Hormone Therapy in Children's Diseases

H. MOMMSEN (*Fortschr. Ther.*, October, 1937, p. 575) points out that during foetal life the child is dependent on maternal hormones, its own not being produced until near term. During gestation the maternal organism shows overproduction of the follicular, luteal, and anterior pituitary hormones (chiefly of placental origin), and sexual hormones are present in the infant's urine at birth. Martin's recommendation in 1929 of administration of these hormones to premature infants has proved its value; they are given preferably in the form of the blood of a pregnant person (according to Hollosi 5 c.c.m. intramuscu-

DIPHTHERIA PROPHYLAXIS

The use of Alum Precipitated Toxoid **A.P.T.** (EVANS)

It is urged that methods of immunisation which do not produce optimal protection be abandoned in favour of methods whose clinical trials leave no doubt about their value. It is because of this that the practice of "one-shot" prophylactic treatment with A.P.T. should be discontinued.

A.P.T. (Evans) is a powerful antigen and immunity resulting from TWO INJECTIONS approaches 100 per cent.

An eminently satisfactory method of immunisation consists of giving two doses of A.P.T. (Evans), the first, 0.1 to 0.2 cc. and the final 0.5 cc., with an interval of two weeks between them.

As an alternative to this procedure, the first dose may with advantage be increased to 0.5 cc., so that in the event of a child not returning for a second injection, the degree of immunity will be higher than that resulting from the smaller initial dose.

For children of 8 years and under.

A.P.T. (Evans) is supplied in:—

Ampoules of 0.5 cc.	2/6 each
Set of 2 x 0.5 cc. immunising doses	4/- per box
Rubber-capped bottles of 5 cc.	16/- each
Rubber-capped bottles of 10 cc.	30/- ..

Made in England at EVANS BIOLOGICAL INSTITUTE by

Evans Sons Lescher & Webb Ltd.
LIVERPOOL and LONDON.

Obstetrics and Gynaecology

16 Follicular Hormone in Urinary Incontinence

HOFFMANN (*Zbl. Gynäk.*, October 30, 1937, p. 2545) has successfully used follicular hormone in the treatment of six cases of incontinence of urine in women about the menopause; some were patients with minor degrees of prolapse, but the incontinence was regarded as chiefly functional. From 20,000 to 50,000 units were given during the week, usually in two injections. Somewhat larger doses cured the diurnal and improved the nocturnal incontinence in a girl, aged 12, who had been unsuccessfully operated on for epispadias. The good results are attributed to an increase by folliculin of the neuro-hormonally regulated tonus of the bladder musculature—evidence of such an action is afforded in recent animal experiments by several workers. The treatment, it is concluded, is worthy of consideration in cases in which mechanical causes for incontinence, cystocele, etc., cannot be found.

17 Tuberculosis and Pregnancy

G. FALKENFLETH (*Ugeskr. Laeg.*, October 14, 1937, p. 1080) has studied the influence of pregnancy on pulmonary tuberculosis in women between the ages of 15 and 50 treated in a Danish tuberculosis hospital between 1923 and 1932. The disease was "open" in 237 cases in which pregnancy did not complicate the tuberculosis, and it was so also in the sixty-three cases in which the patients became pregnant. The mortality was 73 per cent. in the first group, 67 per cent. in the second. Though the figures are too small to justify any statistical conclusion as to the influence—good, bad, or indifferent—of pregnancy on pulmonary tuberculosis, and though in some isolated cases the pregnancy probably did aggravate the tuberculosis, the author is in principle disinclined to advocate the induction of abortion in the hope that it will improve the prognosis. He notes that the cases of pulmonary tuberculosis most likely to be aggravated by pregnancy are for the most part already hopeless. This being so, the arguments for saving the life of a viable infant are strengthened. The problem of combined pregnancy and pulmonary tuberculosis can, he believes, best be solved by giving the patient thorough treatment for her tuberculosis during and after her pregnancy. In his survey of the literature the author points out that Pankow has found pulmonary tuberculosis to run an unfavourable course in 74 per cent. of the women whose pregnancy was not interrupted, and that Scherer has found the same fate to overtake 74 per cent. of the women whose pregnancies were interrupted. These conflicting conclusions are all the more perplexing for the fact that Pankow and Scherer adopted the same clinical classification.

18 Menstruation and Gonorrhoea

V. PUGLISI (*Rinasc. med.*, October 15, 1937, p. 659) studied the effect of menstruation on gonorrhoea by searching for the gonococcus before, during, and after the menstrual period. (1) In twelve cases the examination, which was negative before menstruation, became positive at the onset of the period, and still more so after its termination. In only two cases were the results the same during and after menstruation. (2) In two cases the examination, which had been negative on the first day of the period and throughout its course, became positive after the period. (3) In four cases the examination, which was positive before menstruation, remained so during and after the period. (4) In two other cases the examination for the gonococcus was persistently negative. Puglisi's results therefore lend support to those who emphasize the importance of examination for the gonococcus in connexion with menstruation.

54 D

Pathology

Alcoholic Sleep

I. BOBNOV and N. ASTAPOV (*Arch. Sci. biol.*, 1937, 45, 2, 59) have studied the conditions affecting the action of alcohol on rabbits and dogs. The cerebrospinal fluid of the animals was withdrawn through a cisternal puncture, and twenty-five to thirty minutes later the rabbits were given 4 to 6 c.cm. of pure alcohol per kilogramme of body weight, and the dogs 6 to 8 c.cm. per kilogramme. The alcohol was given in a 30 per cent. solution through a stomach tube. The animals from which the cerebrospinal fluid had been withdrawn became very rapidly drunk, and went into a narcotic sleep lasting five to seven hours. In the control animals the drunkenness was not marked and complete narcosis was not observed. The authors assume that the removal of the cerebrospinal fluid lowers the pH in the region of the brain, and because of that the alcohol penetrates into the brain more easily. The authors have been able to prove this assumption experimentally. "Acidified" dogs became drunk very quickly, while "alkalized" dogs did not seem to be affected by the alcohol.

20 Complement-fixation Reaction in Tuberculous Monkeys

The frequency of tuberculosis in monkeys kept in laboratories and zoological gardens, and the unreliability of the tuberculin reaction in its diagnosis, lend considerable interest to the report by A. URBAIN and J. NOUVEL (*C.R. Soc. Biol.*, Paris, 1937, 126, 25, 165) on the diagnostic value of the complement-fixation reaction. Besredka's technique and antigen were used. Blood was drawn from the saphenous vein, and the serum was heated to 56° C. for thirty minutes in the usual way. Fifty-seven sera from monkeys of different species that were proved at necropsy to be free from tuberculosis gave completely negative results. On the other hand, 139 out of 140 sera from animals that were found at necropsy to be tuberculous yielded positive results. The single negative serum was from a monkey that was suffering from generalized tuberculosis and was on the point of death. It is concluded, therefore, that the complement-fixation reaction is of great value in the diagnosis of tuberculosis in monkeys.

21 Intranuclear Inclusion Bodies

P. K. OLITSKY and C. G. HARFORD (*Amer. J. Path.*, September, 1937, p. 729) have demonstrated that intranuclear inclusion bodies similar to those found in virus diseases may be formed in guinea-pigs as the result of the subcutaneous injection of sterile suspensions of aluminium hydroxide, aluminium, ferric hydroxide, and carbon. Barium sulphate, silver chloride, paraffin, and agar did not evoke inclusion bodies. Generally a foreign-body nodule formed at the site of injection. The tissue response varied with the substance injected, but phagocytic mononuclears and giant cells preponderated in most cases, and their nuclei contained the inclusion bodies when these occurred. Characteristic differences were found between nuclei containing and not containing inclusions. The inclusions were acidophilic and multifocal, and could not be shown to contain nuclear material, "masked" iron, or the substance inducing them. From their general appearance and morphology they were not distinguishable from the inclusions found in virus-containing tissues. Careful search for a virus associated with the inclusions failed to reveal any; the presence of the inclusions must therefore be attributed to the injected foreign substance. Since inclusion bodies of similar appearance and properties may be induced by certain foreign substances as well as by viruses, it is unsafe to infer the presence of a virus from the occurrence of inclusion bodies alone, especially if such a substance as aluminium has been used in grinding tissues to be tested for the presence of virus.

SALTAIR SURGICAL SERVICE

1793

1938

Time marches on Salts' march with Time

ESTABLISHED in the year 1793, Salts' have the Experience which accumulates with Time as well as the Prestige which such a long period of continuous business inevitably confers.

At all periods during its long history the House of Salt has been abreast with the latest developments in the design and production of Surgical Appliances.

Indeed, many of the most successful improvements in these appliances have been evolved by Salts' experts in close collaboration with Medical Men.

And To-day, on the threshold of yet another New Year, Salts' pledge themselves anew to maintain both the Quality of their products and the scrupulously fair Methods of Business which have earned them the confidence of the entire Medical Profession.

SALT & SON LTD. BIRMINGHAM 2

CURTIS - *The Support* that is prescribed by leading London Hospitals

The Curtis Abdominal Model No. 1 is the best method of supporting the lower abdomen without undue constriction. It is scientifically designed to give an even anterior-posterior pressure—at the same time allowing greater freedom to the hips. Model No. 1 is indicated in the treatment of all forms of abdominal ptosis-visceroptosis, enteroptosis and gastropptosis; and it is recommended for support of ventral hernia and scar tissue in the lower abdomen.

For RELIABILITY

"CERABAN" ADHESIVE BANDAGE

The Supplementary or Alternative Treatment to Self-Adhesive Elastic Bandages for
SPRAINS, DISLOCATIONS, CONTUSIONS, SWELLINGS, VARICOSE VEINS, VARICOSE ULCERS, ETC.
Its use eliminates the risk of Dermatitis which so frequently arises from
the application of Self-adhesive Bandages.

"CERABAN," whilst free from rubber, possesses elastic properties and when carefully applied to the limb gives substantial support. It is porous, adhesive, and non-irritating, will not chafe and permits of complete respiration of the skin.

In the treatment of Varicose Ulcers the use of "Ceraban" Bandage eliminates the risk of Dermatitis which occasionally occurs through the application of self-adhesive Elastic Bandages. In the less severe of such cases a distinguished authority writing in the *Lancet*, page 580, Sept. 7th, 1935, issue recommends the use of "Ceraban" Bandage cut in strips as a first and protective dressing prior to covering with self-adhesive Elastic Bandage and in the more serious cases the complete replacement by "Ceraban." It is waterproof, antiseptic, and being spread on an extensible material readily conforms to the shape of the limb and therefore will not slip.

Mild Constipation shown to yield to laxative effect of HOVIS

Many of the mild forms of constipation so prevalent to-day are attributed to the consumption of foods deficient in Vitamin 'B.' In comparing the effects of various kinds of bread it is seen that HOVIS germ bread is superior to either white bread or wholemeal in supplying this deficiency. Whilst white bread contains practically no Vitamin 'B,' HOVIS, with its added

proportion of 25% wheat-germ, supplies an abundance of this essential food-element. Unlike wholemeal bread, HOVIS contains only a minute percentage of bran and indigestible cellulose. In other words its incorporation in the normal diet ensures not only a higher standard of nutrition but easier assimilation and regular evacuation of the intestinal contents

VITAMIN 'B' CONTENT ACTS AS AID TO REGULARITY

Salvitae Promotes Metabolism

To insure a well-balanced metabolism, the tissues need more than heat and energy. Organic elements and inorganic salts must be furnished in proper proportion in order that the electric, magnetic, chemical and other mysterious forces

SALVITAE

locked up in the food molecule and released by digestion may make the metabolic processes effective for health. SALVITAE makes available the minerals to restore and sustain metabolic balance in conjunction with a properly prescribed diet.

Professional samples and literature gladly sent on request.

COATES & COOPER LTD., 94 CLERKENWELL ROAD, LONDON, E.C.1.

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Bland. The iron content remains fresh and unoxidized in-

definitely, and injury to the teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test. The Iron 'Jelloid' Co., Ltd., King George's Avenue, Watford, Herts.

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — **WOODBIDGE, SUFFOLK**

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the

RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 16. (Toll Call from London.)

Proprietors: The Norwood Sanatorium, Limited.

BETHLEM ROYAL HOSPITAL, for Nervous and Mental Disorders,

Monks Orchard, Monks Orchard Road, Eden Park, Beckenham, Kent.

Reg. Tel. Address: Bethlem, Beckenham.

Station: Eden Park (Southern Railway).

Telephone: Springpark 1180-1181.

President: VISCOUNT WAKEFIELD OF HYTHE, G.C.V.O.

Treasurer: SIR LIONEL FAUDEL-PHILLIPS, Bart.

Physician-Supt.: J. G. PORTER-PHILLIPS, M.D., F.R.C.P.

This Registered Hospital is now situated at Monks Orchard, in some 250 acres of park, pleasure, and farm grounds.

Applications can be considered on behalf of patients of the educated classes in a presumably curable condition.

With a view to early treatment voluntary or uncertified patients are admitted.

Patients who can contribute 5 guineas weekly towards the cost of treatment and maintenance may be received as vacancies arise. The Committee will also consider applications for admission at lower rates, and in certain cases will be prepared to admit patients free of charge.

Every facility for specialized investigation and treatment is provided in the Lord Wakefield Science and Treatment Unit. In this unit is found X-Ray and Dental Departments and the Bio-Chemical, Pathological, and Psychological Laboratories.

Furthermore, provision is made for Electro-Therapy and Hydro-Therapy to be carried out in all their forms, and Occupational Therapy under competent instruction is encouraged.

In addition to the Resident Medical Staff, Consultants in special branches of medicine and surgery are available whenever required.

The comfort of sensitive patients is greatly enhanced by the fact that the majority are given single bedrooms.

For forms and further particulars apply to the Physician-Superintendent at the Hospital.

LAVERSTOCK HOUSE

SALISBURY WILTS

PRIVATE MENTAL HOME FOR LADIES AND GENTLEMEN.

Completely up to date. Lovely house and grounds (18 acres). Certified and uncertified cases taken. Facilities for going to the seaside.

PECKHAM HOUSE, 112, Peckham Road, London, S.E. 15.

Telegrams: "Alleviated, London."

Telephone: Rodney 2641-2642.

The above House, which was established in 1826, is an Institution for the care and treatment of persons suffering from mental diseases and nervous disorders. Certified voluntary and temporary patients are received. Separate houses for treatment and accommodation of special cases adjoin the Institution. There is a seaside branch, Kearsney Court, near Dover, to which patients may be sent for treatment or on holiday. Motor and carriage exercise is provided as required. Patients can avail themselves of a course of physical drill. Tennis courts. Entertainments, dances, and indoor amusements held throughout the year. Terms from £3 3s. per week. Illustrated prospectus and further particulars can be obtained from the Medical Superintendent.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER C.M.G., A.D.C.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds, with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath; Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, and X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupation Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone No. 2356 and 2357 Northampton) who can be seen in London by appointment.

COURT HALL, KENTON, near EXETER,

Apply FELLOWSHIP OF MEDICINE, 1, Wimpole Street, London, W.1. (Langham 4266.)

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in April, 1938.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W. 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1938.

ROYAL NAVAL DENTAL SERVICE

Vacancies exist for DENTAL OFFICERS in the ROYAL NAVY, and applications for entry are invited from Registered Dental Surgeons. Candidates must be British subjects of pure European descent, below 28 years of age on the day of entry and physically fit for service in any part of the world. Unmarried candidates are preferred. Candidates will be required to attend at the Admiralty for physical examination and interview by a Selection Board. Copies of the regulations for entry and conditions of Service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W. 1, and from the Deans of Dental Schools.

ROYAL AIR FORCE DENTAL BRANCH

TEMPORARY CIVILIAN APPOINTMENTS

Vacancies exist at certain Royal Air Force Stations for temporary appointments as whole-time civilian dental surgeons. Preference will be given to applicants under 30 years of age.

Further information may be obtained by applying to the Secretary, Air Ministry (D.M.S.), Admiralty House, Kingsway, W.C.2.

CITY OF MANCHESTER

Crumpall Hospital, (1,543 Beds.)

The Public Health Committee invites applications from registered medical men for the post of RESIDENT ASSISTANT MEDICAL OFFICER at the above-named hospital.

The salary for the appointment is £200 per annum, with board, residence and laundry in addition, subject to the Manchester Corporation conditions of service.

The appointment will be made in the first instance for a period of six months, renewable for a further six months, but not renewable thereafter.

Full information and forms of application may be obtained from the Medical Officer of Health, Sunlight House, Quay Street, Manchester, 3, and applications for the post must be received by him not later than January 12th, 1938.

F. E. WARBRECK HOWELL,

Town Hall, Manchester, 2, Town Clerk.

December 2nd, 1937

GOVERNMENT OF INDIA

1. Applications are invited from women candidates for the appointment of PROFESSOR OF MATERNITY AND CHILD WELFARE at the ALL-INDIA INSTITUTE OF HYGIENE AND PUBLIC HEALTH, Calcutta.

2. Candidates must possess a registrable medical qualification and must have experience of the executive and administrative aspects of Maternity and Child Welfare. Preference will be given to candidates possessing also experience in directing or conducting research and in lecturing to students.

3. Agreement for five years in the first instance pay according to age and qualifications in scale Rs. 450, rising by triennial increments of Rs. 50 to Rs. 550 a calendar month, plus Overseas Pay of Rs. 100 when salary is Rs. 600 or less, or Rs. 150 when salary is Rs. 650 or more, (Rupee = 1s. 6d. approximately). House allowance, Provident Fund first-class passage to India and return passage on satisfactory termination of service (overseas pay and return passage admissible only to appointee of non-Asiatic domicile).

4. Further particulars and forms of application may be obtained, on application by postcard, from the High Commissioner for India, General Department, India House, Aldwych, London, W.C.2. Last day for receipt of completed applications January 17th, 1938.

CITY AND COUNTY OF THE CITY OF CHESTER

DEPUTY MEDICAL OFFICER OF HEALTH AND DEPUTY SCHOOL MEDICAL OFFICER.

Applications are invited for the above-mentioned appointment from duly registered medical practitioners of not more than 35 years of age.

The salary offered will commence at £500 per annum rising by annual increments of £25 to a maximum of £700 per annum.

Further particulars of the duties, terms and conditions of the appointment and application form can be obtained from the Medical Officer of Health, Town Hall, Chester, to whom applications (to be made on the form provided) accompanied by copies of three recent testimonials are to be delivered not later than Wednesday, January 12th, 1938.

The successful applicant will be required to pass a medical examination and to contribute 5 per cent of his salary to the Council's superannuation fund.

Conveying directly or indirectly will be a disqualification.

I. H. DICKSON,

Town Clerk

SURREY COUNTY COUNCIL

WARREN ROAD HOSPITAL, GUILDFORD

APPOINTMENT OF MEDICAL SUPERINTENDENT.

Applications are invited from registered medical practitioners for the appointment of Medical Superintendent at the Warren Road Hospital, Guildford (255 beds), which at present forms part of a Public Assistance Institution, but which will, subject to the Minister of Health's approval, be appropriated for Public Health purposes on April 1st, 1938. The Medical Superintendent will be required to commence duty as from the date of appointment.

The Medical Superintendent may also be required to act without additional remuneration as Medical Officer of the remainder of the Institution accommodating 153 persons, which will be retained for Public Assistance purposes.

Candidates should have had considerable experience in Hospital Administration, and should possess a higher qualification.

The salary will be at the rate of £500 per annum, rising, subject to satisfactory service, by annual increments of £50, to a maximum of £1,000 per annum.

The Medical Superintendent will in due course be provided with an unfurnished house (free of rates), valued at the rate of £100 per annum, in which he will be required to live when it is provided. Until such time the cash value of this emolument will be paid to the Medical Superintendent.

The appointment will be subject to the staffing regulations of the Council, and the officer appointed will be required to devote his whole time to the service of the Council, and any fees he may receive must be paid into the County Fund.

The officer appointed will be required to pass a medical examination, and the post will be a designated one for the purposes of the Local Government and Other Officers' Superannuation Acts.

Applications, stating age, qualifications and experience, and enclosing copies of not more than three recent testimonials, should be endorsed "Medical Superintendent" and sent to the County Medical Officer, County Hall, Kingston-upon-Thames, so as to reach him not later than 12 noon on January 8th, 1938.

Conveying will disqualify.
County Hall, DUDLEY AUKLAND,
Kingston-upon-Thames, Clerk of the Council,
December 16th, 1937.

THE HOSPITAL FOR SICK CHILDREN
GREAT ORMOND STREET, LONDON, W.C.1

MEDICAL SCHOOL FOR POST-GRADUATES

THE HOSPITAL CONTAINS 257 BEDS, with an average admission of over 7,000 in-patients per annum, whilst in the year 1907-8 about 15,000 new patients are seen each year.

THE MEDICAL SCHOOL is recognised by the Universities of Oxford, Cambridge, and London, and by the Conjoint Board of the three London Teaching Hospitals where students receive instruction in the diseases of children for such period as is required.

POST-GRADUATE INSTRUCTION, open to all qualified medical men and women, is given daily at both morning and afternoon sessions. Morning sessions 10 to 12 noon include Medical and Surgical Out-patient Clinics; Ear; Nose and Throat Clinic; and Ophthalmology. Afternoon sessions include Ward Visits and Surgical Operations; Eye Clinic once a week; and Post-graduate Clinics once a week; Morbid Anatomy Demonstration, Wednesday 11 to 12 noon. Instruction is also given in the Venereal Disease Department, and in the use of anaesthetics in dental and tonsillectomy operations.

There are three terms yearly, each of approximately 13 weeks, during which lectures (particulars of which are published in prospectus) are given on Thursday afternoons:—Clinical 2 to 3 p.m. and Clinical-pathological or Biochemical 3 to 4 p.m.

For One week, 11 guineas; two weeks, £3 3s.; one month, £5 5s.; two months, 7½ guineas; three months, or whole term, £10 10s. Clinical Clerkships in the wards are available for fourth and fifth year undergraduates. Special Clinical Assistantships for Post-Graduate Students for periods of three months and upwards can be arranged.

SPECIAL COURSES IN PRACTICAL PATHOLOGY, consisting of six demonstrations, are also given at the Hospital. These are designed to show the methods as can be usefully carried out away from a laboratory and are of general application. Fee for each course, £5 10.

COPIES OF THIS may be obtained from the Secretary at the Hospital.

Applications, stating age, qualifications, experience, age, and nationality, to be sent to Dr. Harbinson, Smedley's Hydro, Matlock.

CITY OF LEEDS.

KILLINGBECK SANATORIUM.

SENIOR ASSISTANT RESIDENT MEDICAL OFFICER.

Applications are invited from registered medical practitioners (male) for the post of Senior Assistant Resident Medical Officer at the Tuberculosis Sanatorium, Killingbeck (242 beds).

Applicants must be unmarried, and preference will be given to those who have held a general hospital appointment and had experience in the treatment of pulmonary and surgical tuberculosis in sanatoria. Under the present salaries scale of the Council, the commencing salary for the post is £425 per annum and the maximum salary £500 per annum, with board, residence and laundry, these emoluments being valued for superannuation purposes at £120 per annum, together with annual increments of £25 subject to satisfactory service. The first increment will take effect on April 1st following the completion of twelve months' service.

The person appointed will be required to pass a medical examination and to contribute to the Superannuation Fund established under the Local Government and Other Officers' Superannuation Act, 1922.

Applications, on a form to be obtained from the undersigned, together with copies of three recent testimonials, and endorsed "Tuberculosis Officer," must be received at the Health Department, 12, Market Buildings, Vicar Lane, Leeds, 1, not later than 10 a.m. on Saturday, January 15th, 1938.

Canvassing in any form, either directly or indirectly, will be a disqualification.
J. JOHNSTONE JERVIS, Medical Officer of Health.

COUNTY BOROUGH OF WALSALL.

MANOR HOSPITAL

ASSISTANT MEDICAL OFFICER

Applications are invited from duly qualified persons for the appointment of Assistant Medical Officer at the above Hospital, which contains 303 beds. (Admissions number nearly 4,000 yearly.) The applicants should have had experience in general medicine.

Commencing salary £150 per annum, rising by annual increments of £25 to a maximum of £450 per annum, together with the usual residential allowances.

The appointment will also be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

The person will be required to act under the general direction of the Medical Superintendent, from whom any further particulars of the appointment may be obtained.

Forms of application may be obtained from the undersigned, and should be returned to me, accompanied by copies of not more than three recent testimonials, not later than January 8th, 1938.

JAMES A. M. CLARK, Medical Officer of Health.

Health Department,
Council House, Walsall.
December 23rd, 1937.

BOROUGH OF WORTHING.

MEDICAL OFFICER OF HEALTH.

Applications are invited from duly registered medical practitioners possessing a diploma in Sanitary Science, Public Health or State Medicine for the appointment of Medical Officer of Health of the Borough.

Salary £1,000 per annum, rising by annual increments of £50 to a maximum of £1,200 per annum, plus motor-car allowance of £50 per annum.

Terms and conditions of appointment and forms of application will be supplied on receipt of a stamped and addressed foolscap envelope.

Applications, with not more than three recent testimonials, must be received by the undersigned not later than January 15th, 1938.

Town Hall, J. KENNEDY ALLERTON, Town Clerk.
Worthing, December, 1937.

BRITISH POSTGRADUATE MEDICAL SCHOOL.

Applications are invited from fully qualified medical practitioners for the post of **CASUALTY OFFICER**, to commence duty on March 1st, 1938.

The appointment is for six months and non-resident. Salary is at the rate of £150 per annum, and the post is specially suited to candidates studying for higher qualifications.

Applications, accompanied by two testimonials, should be addressed to the Dean, British Postgraduate Medical School, Ducane Road, W.12, to arrive not later than the first post on Monday, January 10th.

BOROUGH OF MORLEY.

APPOINTMENT OF ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from registered medical practitioners (male or female) for the above-named post. It is desirable that applicants should hold a Diploma in Public Health.

Applicants should have had at least three years' experience in the practice of their own profession and have had special experience in Maternity, Child and Infant Welfare work and in the administration of Dental and other Anaesthetics.

The person appointed will be required to work under the direction of the Medical Officer of Health and the School Medical Officer and to devote the whole of his or her time to the duties of the office, which will consist chiefly of School Medical, Maternity and Child Welfare work together with such other duties in the Public Health Department as may be required.

The appointment will be a designated post under the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass a medical examination.

Salary will be at the rate of £500 per annum, rising, subject to satisfactory service, by annual increments of £25 to £700 per annum. The appointment will be determinable by one month's notice on either side.

Forms of application may be obtained from the undersigned to whom they should be returned, completed, in a sealed envelope endorsed "Assistant Medical Officer," together with copies of three recent testimonials, on or before January 10th, 1938.

E. V. FINNIGAN, Town Clerk.
Town Hall, Morley, Leeds.

CITY AND ROYAL BURGH OF DUNFERMLINE.**RESIDENT OBSTETRICAL OFFICER.**

Applications are invited for the post of Resident Obstetrical Officer at the Maternity Hospital.

Candidates should have held previous resident appointments in a Maternity Hospital and have had experience in ante-natal and post-natal work. Preference will be given to candidates who hold or are reading for membership of the College of Obstetricians and Gynaecologists. The officer appointed will be called on to act as outdoor consultant under the Maternity Services (Scotland) Act, 1937, and will also be required to assist in the Maternity and Child Welfare Scheme and to undertake such other duties as may be assigned to him by the Medical Officer of Health.

The salary will be at the rate of £400 per annum rising by annual increments of £25 to £475 per annum with emoluments valued at £150 per annum and travelling expenses.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination. The appointment will be terminable by three months' notice on either side.

Forms of application may be obtained from Dr. C. Barclay Reekie, Medical Officer of Health, 1, Douglas Street, Dunfermline, and must be returned to him, accompanied by copies of three recent testimonials, not later than January 15th, 1938. Canvassing will disqualify.

ANDREW SHEARER, Town Clerk.
City Chambers, Dunfermline.
December 20th, 1937.

BOVRIL MEDICAL AGENCY, LTD.

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, LESQUARE, LONDON.

Chairman and Managing Director, Dr. J. FIELD HALL. Telephone: TEMPLE BAR 1616 (3 Lines).

The maximum commission payable on the sale of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency is £50 (fifty pounds), which sum covers goodwill, drugs, surgery fittings, fixtures and furniture, instruments and book debts, but not house property. Schedule of Terms will be forwarded on application.

Accountancy and legal services furnished by the Agency, where desired, at moderate inclusive charges. No charge is made to Principals for the introduction of Locum Tenens or Assistants.

1. SOUTH COAST SEAPORT.—Old-established mixed-class PRACTICE producing for past 12 months over £3,000. Panel of about 1,600. Various appointments. Well situated good modern house with 3 reception and 5 bedrooms. Central surgery rented at £60 p.a., part sub-let. Premium 2 years' purchase. Up-to-date hospital and Vendor on staff.
2. DORSET COAST.—PARTNERSHIP.—A ONE-THIRD SHARE with increase later in a well-established Practice averaging about £3,000 p.a. Panel of over 2,700 and P.M.S. about 1,000. Various appointments producing £250-£300 p.a. Low expenses. Suitable house with 5 bedrooms, etc., can be purchased or rented. Premium 2 years' purchase.
3. RIVERSIDE TOWN.—PRACTICE has been established about 60 years. Receipts approximately £1,500 including 450 panel patients. House contains 2 reception and 5 bedrooms, etc. Leasehold for sale or might be rented. Premium 2 years' purchase or near offer.
4. SOUTH COAST.—Favourite town.—Old-established PRACTICE producing over £1,700 p.a., including a Panel of about 1,500 and appointments worth approximately £300 p.a. Scope for surgery and prospect of hospital appointment. Low expenses. House containing 2 reception, 6 bedrooms, 2 bathrooms, consulting room, separate surgery, with garden and garage, obtainable on lease. Premium 2 years' purchase, to include book debts and drugs.
5. NORTH LONDON.—Well-established middle and working-class PRACTICE at present producing about £600 p.a., with prospects of increase, particularly for Panel work. The Panel has only been recently started. Suitable accommodation available on rental. Any reasonable offer accepted for a quick sale, as Vendor wishes to take up an appointment.
6. LEICESTER.—Country PRACTICE.—Old-established for disposal as Vendor is retiring. Receipts approximate about £450 last year, including Panel of 280 patients. Expenses low. House on rental. Premium 1½ years' purchase.
7. NORTH LONDON SUBURB.—Recently established PRACTICE in fast developing area. Receipts last year about £720, including Panel of about 200 patients. Architect-built modern house with ample accommodation. Freehold for sale. Premium £850 or near offer.
8. GLOS.—Sound old-established PRACTICE in beautiful country district, averaging for the past four years about £1,300 p.a. Panel of over 1,100 and appointments worth about £80. Very nice house, in its own grounds, containing 2 reception, 5 bedrooms, etc. Freehold for sale. Premium 2 years' purchase.
9. SOUTH-EASTERN SUBURB.—Well-established PRACTICE producing for last twelve months over £1,650, including Panel of 1,050. Low expense. Convenient house with 2 sitting, 3 bedrooms, etc., garden and garage. Price £1,240. Premium £3,300.
10. LONDON, EAST.—Exceptionally sound old-established PRACTICE in populous area averaging for past 3 years over £2,240 p.a. Panel of approximately 3,500. Suitable house with excellent professional accommodation can be rented at £75 p.a.
11. FAVOURITE RESIDENTIAL TOWN WITHIN 70 MILES OF LONDON.—Old-established better-class non-panel PRACTICE producing over £1,500 p.a. A certain amount of electrical work is undertaken. Fees 5/- to 21/-. House can be rented at £180 p.a. Premium £6,000.
12. DUTYING NORTHERN PRACTICE M.S. £188 p.a. Suitable
13. LANCs.—TOWN.—Easily worked, mostly non-dispensing practice, averaging about £1,000 p.a. including panel of about 375. Low expenses. Suitable house available with consulting and waiting rooms, 2 reception, 3 bedrooms, maid's room, etc. Large garden. Garage. For sale or can be rented. Premium 1½ years' purchase. Good scope.
14. LEEDS.—PARTNERSHIP with succession in 6 or 12 months. A 2/3rds share is offered in an old-established Practice which has been held by the vendor, who is now specialising, for the past 2 years. Receipts for last year amounted to £1,176, including £492 from a Panel of about 1,150 patients. Suitable house available, freehold £900. Premium 1½ years' purchase.
15. LANCs.—Old-established PRACTICE available owing to ill-health of vendor. Receipts for last year £662, including Panel of about 620 patients. Freehold house with 2 reception, 3 bedrooms and 2 sitting. There is stated to be good scope for increase as the receipts were formerly £1,200 p.a. Price for Practice and house £2,100.
16. WEST OF ENGLAND.—Good-class residential town.—A ONE-THIRD SHARE with increase up to one-half is offered in a better middle-class Practice at present averaging £1,200 p.a. Appointments worth about £350. Panel of 300 patients. Fees 5/- to 21/-. Flat available in vendor's house for single man. Rent £40 p.a., inclusive of rates.
17. NORTH WALES.—Good-class long-established PRACTICE in very attractive residential and seaside resort. Cash receipts for last 16 years over £1,200 every year. Panel 425. Good house with 2 small gardens to rent or purchase, freehold. Socially very pleasant. Premium £1,800. Vendor going abroad.
18. HERTS.—Country town on outskirts of London.—Very old-established PRACTICE held by vendor for 30 years. Gross cash receipts about £1,000 p.a., including Panel of 600 patients. Nice house with 2 reception, 5 bedrooms, etc. Good garden on rental. Premium 2 years' purchase.
19. NORTH CORNWALL.—Country PRACTICE in picturesque district near coast and within easy reach of two good towns. Stated to produce nearly £1,000 p.a., including Panel of £320.
20. HANTS.—Recently established PRACTICE in pleasant locality. Earnings for the first year about £230, with Panel of 80 and increasing. Stated to offer considerable scope for development. Very nice small house can be rented. Moderate premium for quick sale, as vendor wishes to take up another appointment.
21. WITHIN 25 MILES OF LONDON.—PARTNERSHIP, with surgical scope. A one-fourth share, with increase later, is for disposal in an old-established Practice, producing about £4,800 p.a. Fees 3/6 to 21/-. A suitable house can be secured. Incoming partner must have a Fellowship, be experienced and not over 35 years of age.
22. LONDON, SOUTH-EAST.—STEADY DISTRICT.—Recently established Practice producing for last 12 months £1,387. Sale 2 reception, 3 bedrooms, etc., garden, garage. Can be rented on lease. Premium £2,000.
23. COAST TOWN.—Old-established PRACTICE held by vendor for 3½ years, who now wishes to specialise. Gross receipts for last year approximately £2,183, including Panel of 770 and appointments producing about £100 p.a. Visits from 5/-. Good house available, containing 2 reception, 7 bedrooms, Professional accommodation, etc. Freehold £1,100. Premium 2 years' purchase or near offer.
24. MONMOUTHSHIRE.—Established over 20 years, producing for last 12 months £1,100. Fees 3/6 to 21/-. Good house with 2 reception, 3 bedrooms, etc., garden, garage. Can be rented on lease. Premium 1½ years' purchase.
25. WEST COAST.—ICE, producing about £1,930 p.a. on rental at £50 p.a. Premium 12 years' purchase.
26. EASTERN COUNTIES.—Mixed-class PRACTICE in pleasant agricultural district producing for last twelve months over £1,300 p.a. Fees 3/6 to 21/-. Nine hours in week ending with 2 reception, 3 bedrooms, etc. Freehold for sale. Premium 2 years' purchase.
27. CROYDON AREA.—Rapidly increasing PRACTICE producing about £1,800 p.a. Panel of about 1,100. Fees 1/6 to 3/6, with visits from 2/6 to 5/-. Practically all cash. Vendor specialising in midwifery. Suitable house available on rental. Premium £3,200.
28. SUSSEX COUNTRY.—Good NUCLEUS with scope for further increase. Receipts: 1935, £467; 1936, £628; 1937 for 7 months, £452. Panel produces about £267 included in above. Good house on rental.
29. NORTH LONDON.—Middle and better-class PRACTICE suitable for medical man with qualified wife or for working with a lady assistant. Gross cash receipts for last 12 months £1,681. Panel of 320, appointments worth about £70 p.a. Visits 5/- to 7/6. Good house with reception, 3 bedrooms, etc. Professional rooms, small garden, garage. Freehold for sale or might be rented. Premium 2 years' purchase or near offer.
30. PARTNERSHIP.—LONDON, EAST.—A HALF-SHARE of middle and working-class Practice, producing for immediate past 12 months £4,567 p.a. Panel of over 5,000. Suitable house can be obtained.
31. DEVON, SOUTH COAST.—A well-established good-class entirely private PRACTICE producing for the past 12 months about £1,000. Panel could be had if desired. Fees 2/6, 3/6, 5/- and 7/6, with a few visits up to 21/-. Non-dispensing. Suitable house containing consulting room, 2 reception rooms, 6 bedrooms, for sale. Freehold £1,400. Partnership introduction. Would be suitable for ex-M.S. or similar.
32. LONDON, E.2.—Lock-up PRACTICE established 80 years for disposal. Income about £800-£900 p.a., with Panel of about 1,150 patients. Fees 2/6 and 3/6. Visits from 3/6. Suitable accommodation available containing consulting room, dispensary, waiting room, the remainder being sub-let for £280 p.a. Rent and rates £230 p.a. Premium 2 years' purchase to include about £150 fittings, fixtures, drugs, etc.
33. CITY PRACTICE.—Lock-up, hours 10-1 and 5.30-6.30, producing about £1,500 p.a., with small club bring in about £85 p.a. House available, contains Professional accommodation, reception room and 3 bedrooms and maids' room, bathroom. For sale or might be rented. Premium £3,000.
34. ASSISTANTS REQUIRED.—1. SURREY.—Outdoor, with view to partnership. Good class Practice. Pref. Graduate, accustomed to better-class work. 2. GLOS.—Outdoor, £436 p.a., plus percentage and car allowance. 3. HERTS.—Indoor, with view to partnership. £300 p.a. 4. WORCS.—Outdoor, £450 p.a., plus car allowance. 5. HUNTS.—Outdoor, £400 p.a., with unfurnished cottage. Scope for surgery. View to partnership.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

WHY AGAROL BRAND COMPOUND FOR CONSTIPATION ?

Among the curative measures advocated for overcoming constipation, none has proved more consistently successful than AGAROL—the original emulsion of mineral oil and agar-agar with phenolphthalein. Agarol renders the faecal mass plastic and pliable with unabsorbable moisture. It lubricates the intestinal tract and

gently stimulates peristalsis, ensuring an easy and complete evacuation.

Used over a reasonable period, Agarol gradually restores muscular tone and functional activity of the bowel, with the gratifying assurance that natural evacuation will follow without the need for further medication.

Supplied in 4½ oz., 7½ oz. and 17 oz. bottles.

Agarol is not advertised to the public.

Trial supplies to Members of the Medical Profession on request.

"To my patients probably the most appreciated drug which we have come to use frequently in the last two years is ergotamine tartrate which in most cases will bring prompt relief to sufferers from migraine."—*Clin. Med. and Surg.*, Jan., 1937.

MIGRAINE

Clinical experience of recent years has provided ample proof of the fact that no other drug has given results so uniformly successful as FEMERGIN (ergotamine tartrate) in the treatment of migraine. Even patients who have long been subject to migraine attacks have in the majority of cases obtained almost miraculous relief following the administration of FEMERGIN.

The dosage should be varied to find the smallest amount that will be effective, but generally 0.25 to 0.5 c.c. by hypodermic injection will suffice to abort or cut short an attack. In mild cases satisfactory relief may be obtained from oral administration.

YES

YOU CAN SAFELY PRESCRIBE THIS TEA FOR ALL YOUR PATIENTS

Not because it is specially prepared in any way whatever, but simply because it is harmless to the most delicate digestion. The Doctor's China Tea is a blend of the choicest teas that China grows—teas which contain comparatively so little tannin that they can be enjoyed by all. For over a quarter of a century The Doctor's China Tea has been recommended by the medical profession—even in cases of dyspepsia and gastritis. A generous free sample will be sent to any doctor who would like an opportunity of trying the tea.

THE

DOCTOR'S CHINA TEA

1. WEIGHT OF SUPPORT ON PELVIC GIRDLE

Each Spencer is designed to place the weight of the abdominal support on the pelvic girdle—NEVER on the spine at, or above, the lumbar region.

2. ABDOMINAL UPLIFT WITHOUT COMPRESSION

In a Spencer the abdominal support is a separate section which is shaped and sized to the individual needs of the patient. It is instantly adjustable from the outside to any degree required, providing specific uplift without compression.

3. POSTURE IMPROVEMENT

All Spencers are designed to improve posture. Spencer Individually Designed Supports, which provide abdominal support and uplift without back strain, guide the body into improved posture.

THESE 3 ESSENTIALS are assured only when a support is individually designed for the patient

Spencer Supports are distinguished from ordinary supports in that every section, every line is individually designed, cut and made to meet the particular needs of the one patient who is to wear it. Hence, they fit exactly on the figure and are perfectly comfortable. All Spencers are light in weight, flexible, easily laundered and guaranteed NEVER to lose their shape. (Any support that loses its shape loses its effectiveness. Spencers are,

to our knowledge, the only garments that carry a guarantee to hold their shape until worn out.) They are well liked by patients in all walks of life because they are economical and provide graceful carriage. Spencer Supports are individually designed for: Breast Conditions, Hernia, Sacro-iliac and Lumbo-Sacral Strain, Enteropneosis and intestinal Stasis, Movable Kidney, Pregnancy and Postpartum Support.

BEWARE OF SUBSTITUTION.—Spencer Corsets Ltd. regret the necessity of warning the medical profession that in several instances where doctors have specifically prescribed a Spencer Support, a corset of another make has been substituted, and, because its makers do not understand the Spencer principles of individual designing, has been unsatisfactory. Every genuine Spencer Support bears the SPENCER Label.

Trained Spencer Corsettières are resident throughout the Kingdom. Name of nearest gladly supplied on request.

A scientifically trained Spencer Corsettière will call at your surgery or at your patient's home to take measurements under your supervision.

MAW STEROTHERM

HOT AIR ELECTRIC AUTOMATIC STERILIZER

Patent No. 427581

Maw Sterotherm Automatic Sterilizers have been installed in the London, Westminster and many other Hospitals, Surgeries, etc., throughout the country and are functioning with the utmost efficiency. The special features of the Sterotherm ensure complete sterilization of Instruments, Dressings, Oils, etc., by the Hot Air method. It is the ideal unit where economy of space and outlay are essential.

May we send you details or arrange demonstration?

SPECIAL FEATURES

- Efficient Sterilization
- Automatic regulation of temperature.
- No supervision necessary while in use
- Very small current consumption.
- Articles in apparatus remain sterile until required, as closure is bacteria-proof.
- Dressings quite dry after leaving Sterilizer
- Convenient size—length 16½ in., diameter 9½ in.

PRICE £20

The First MAINS DEAF AID AMPLIVOX MODEL M8

AMPLIVOX LTD.

106, George Street, Portman Sq., London, W.1. Telephone: Welbeck 2591/2
19, St. Vincent Place, Glasgow, C.1. Telephone: Central 3097
62a, Bold Street, Liverpool, 1. Telephone: Royal 4944

THE AMPLIVOX is obtainable in the United Kingdom only from the manufacturers—AMPLIVOX, LTD.—and from Messrs. T. Hawksley, W. H. Pettifor, and Aids for the Deaf. There are appointed representatives in Australia, New Zealand, Canada, South Africa, India, the I.F.S., Northern Ireland, France, Holland, Norway, Sweden, and Denmark.

For the person who puts sound quality first in purchasing a hearing aid the model M8 AMPLIVOX is the obvious choice. This instrument is designed to run entirely from the electric mains, there being no batteries whatsoever. The piezo-electric crystal microphone is a separate unit to place on the table; the amplifier weighs less than 4 lbs. Through the use of unlimited voltage the clarity and power are of a higher order than with any other electrical hearing aid. The amplifier embodies automatic volume compression and the exclusive AMPLIVOX feature of a 3-position switch permitting adjustment of the frequency characteristic to compensate for the most common forms of hearing loss. This instrument will pay for itself in a short time through the economy of upkeep (1d. per 200 hours). For the home, office, etc., it is indispensable.

An AMPLIVOX deaf aid will gladly be sent for clinical test, and may be taken away for a week on trial before purchase for a small fee.

A copy of the AMPLIVOX brochure describing all models and giving much interesting information on hearing aids will be sent on application.

AN IMPROVED May Ophthalmoscope

At only slightly increased cost the Gowlland Ophthalmoscope can now be supplied having illuminated and magnified numbers. These are magnified to nearly twice the size of the older pattern and positioned well away from the sight hole; they are brilliantly illuminated, can be read easily in the brightest surroundings and cannot possibly interfere with the observation. The illumination of the numbers is effected by the ordinary Ophthalmoscope Lamp, and there is no additional load on the battery.

The patch of light projected by this instrument is bright, circular and absolutely homogeneous, making close examination easier. The reflecting prism is adjusted so that there are no shadows on the fundus, and corneal glare is reduced to the lowest possible amount. The focussing system (Patent No. 358766) and movements are exceptionally smooth in use.

WITH
ILLUMINATED
AND
MAGNIFIED
NUMBERS

Gowlland
electric diagnostic instruments
can be obtained from all Surgical Supply Houses.

ERGOMETRINE B.D.H.

Ergometrine is the rapidly-acting water-soluble alkaloid of ergot described by Dudley and Chassar Moir (Brit. Med. Journ., 1932, I, 1119). It is administered as a routine after parturition, and as an emergency measure during postpartum hæmorrhage.

Ergometrine is as effective orally as by injection, and there is very little reduction in the delay of onset of action when parenteral administration is substituted for oral administration. Indeed, injection need only be

employed if the patient is unable to swallow or to retain an orally administered medicament.

Ergometrine B.D.H. is available in tablets for oral administration and for injection; it is available also in ampoules for intra-muscular or intravenous injection.

For the production of the prolonged contractions required during the puerperium Ergotoxine Ethanesulphonate B.D.H. is available.

NOVASORB

(Magnesium trisilicate Evans)

A SAFE ANTACID & ADSORBENT

For the treatment of hyperacid gastritis,
acid fermentation and gastric ulcer

Novasorb is produced by methods which ensure an
optimum clinical value with freedom from any un-
favourable secondary effect. Even when given in
quantity sufficient to neutralise free hydrochloric
acid entirely, it cannot cause alkalosis.

DOSAGE: Approximately one teaspoonful, modified according
to the necessities of each case. Overdosage is not
harmful.

Evans Sons Lescher & Webb Ltd.
Liverpool and London

NOVASORB is issued in bottles:
4-oz. 2/6; 8-oz. 4/9; 16-oz. 9/-
5-lbs. (Hospital size) 40/-
and in tablets: tins of 48, 2/3

A + B + C + D

NESTROVITE

contains four

essential vitamins

in definitely stated

units

Every packing of this new vitamin concentrate gives the doctor the information he has a right to expect—no vague assertions, such as “rich in vitamins,” but clear, precise statements concerning the 4 vitamins, A, B₁, C and D present in every bottle of ‘Nestrovite’ Emulsion and in every ‘Nestrovite’ Tablet. ‘Nestrovite’ in Emulsion form is ideal for the baby and young child, while ‘Nestrovite’ Tablets are more convenient for youth and adult.

DOSES

Infants 1 teaspoonful
Nestrovite
Emulsion
daily.

We Suggest that You Recommend THE ORIGINAL PINEAPPLE JUICE FROM HAWAII

Here is a typical Analysis of Dole Pineapple Juice:

Moisture	85.39%
Ash	0.4
Fat (ether extract)	0.3
Protein (N x 6.25)	0.3
Crude fibre	0.02
Titratable acidity as citric acid	0.9
Reducing sugars as invert sugar	12.4
Carbohydrates other than sugars (by difference)	0.38

THE SURF RIDER.—Surfing, the sport of Hawaiian kings in olden days, was one of the favourite pastimes. Owing to the way the surf breaks on the reef, Waikiki is the only place in the world where this sport is indulged in under ideal conditions. It is a marvellous sight to see the upright gleaming brown bodies of the native surfers come riding swiftly shoreward on a giant comb.

P.S. Just write to us on your letterhead and we will be pleased to send you free a sample tin of delicious Dole Hawaiian Pineapple Juice.

Prescribing a Laxative

When, as frequently happens, the Physician is called upon to prescribe a laxative for prolonged personal use by the patient, Andrews Liver Salt merits special consideration. The main characteristics of this tonic laxative, listed below, suggest its wide range of suitability.

- 1 Andrews is pleasant-tasting. All ages take it readily.
- 2 Andrews causes none of the griping or other discomforts which often create reluctance to continue the use of the more drastic purgatives. Its laxative action is due to the presence of magnesium sulphate and other salts, which increase the fluid content of the bowel by Osmotic action, and so lead to painless, easy evacuation.
- 3 Because of its natural and non-habit-forming action, Andrews—in suitable doses—may be taken with every confidence by the physically weak and during pregnancy. This tonic laxative does not affect adversely the secretion of milk in nursing mothers. Indeed, the quantity of water taken with Andrews Liver Salt contributes to the extra liquids a nursing mother should take.
- 4 Andrews is particularly valuable in the case of patients liable to digestive trouble. The carbon dioxide which is liberated when Andrews is dissolved in water has a soothing effect on the stomach and a physical cleansing action on the stomach walls. Additionally, Andrews corrects excess acidity, stimulates the liver and promotes the flow of bile.
- 5 Andrews creates no dependence on artificial aid, but can be discontinued when the need for it ceases.

DIPHTHERIA PROPHYLAXIS

The Use of Alum Precipitated Toxoid

A.P.T. (Evans)

For children of 8 years and under

A.P.T. (Evans) is a powerful antigen; immunity resulting from TWO INJECTIONS approaches 100 per cent. A dosage of 0.1 cc. to 0.2 cc. followed by 0.5 cc. after two weeks is recommended.

As an alternative to this procedure, the first dose may with advantage be increased to 0.5 cc. so that in the event of a child not returning for a second injection, the degree of immunity will be higher than that resulting from the smaller initial dose.

A.P.T. (Evans) is supplied in:—

Ampoules of 0.5 cc.	2/6 each
Set of 2 x 0.5 cc. immunising doses	4/- per box
Rubber-capped bottles of 5 cc.	16/- each
Rubber-capped bottles of 10 cc.	30/- each.

Convalescence

In convalescence a tonic is required that will co-operate with, and augment, the natural recuperative powers of the body, rather than one which will have only an immediate stimulating effect. In the latter case there is always the danger of disappointment, due to an artificial improvement that the natural powers are unable to stabilise.

Medical evidence extending over many years has established the value of Sanatogen in promoting convalescence. In "The Elements of Pharmacy, Materia Medica and Therapeutics", Sir William Whitla writes:—

"... The interesting and valuable researches conducted by Tunncliffe and Beddoes upon metabolism, in which Sanatogen was experimented with, establish the fact that its organic phosphorus is almost entirely assimilated when the food is administered in the amount necessary for the needs of the body. When given in addition to other food, the amount of nitrogen and phosphorus retained in the organism is increased; the tissue metabolism is more complete, the constituents of the ordinary food being more thoroughly utilised; appetite is increased and the body weight augmented."

Similarly gratifying observations are constantly being notified, and, as Sanatogen is entirely free from fats, sugars and carbohydrates, it can safely be prescribed in all types of cases. It is rapidly and easily digested and assimilated, even in cases exhibiting severe gastric inflammation, and for this reason it is a valuable addition to enemata. It can be added to any non-acid beverage or food, and, consequently, monotony in its administration can always be avoided.

CADBURY BROS. BOURNVILLE ENGLAND

FOR EFFECTIVE CONTROL OF PAIN

AMONG the many and diverse analgesics which have been evolved by modern chemical research, acetyl-salicylic acid retains its reputation as one of the safest and most effective. Its tendency to liberate salicylic acid—the irritant properties of which are well known to physicians—has, however, caused many to hesitate to employ it as widely as it deserves. Exhaustive trial in hospital and private practice proves that "Alasil" definitely solves the problem of administering acetyl-salicylic acid in an effective form, being free from the risk of irritating the stomach or bowels or of causing general reactions.

A supply for clinical trial with full descriptive literature sent free on request.

In "Alasil" the desirable therapeutic effects of acetyl-salicylic acid are well exhibited by its calcium acetyl-salicylate moiety, while the presence of "Alocol" (Colloidal Hydroxide of Aluminium), a powerful gastric sedative and antacid, obviates any tendency to gastric irritation. The superior absorbability of "Alasil" over ordinary salicylate compounds and its freedom from the risk of liberating free salicylic acid in the stomach have been well proved by careful experimentation. "Alasil" can be prescribed with perfect safety to patients of all ages and in larger doses than ordinary salicylate compounds.

RELIABLE VITAMIN PROTECTION AGAINST WINTER

Flexibility
more important than
extreme concentration

★★★ To protect the susceptible at this time of year, to shorten the course of an early cold, or to check recurrent infection, the immediate administration of Adexolin vitamins A and D is urged. Four to five Adexolin capsules daily, followed by a routine dosage (one capsule daily) has proved to be a reliable measure. Adexolin serves to build up a nutritional barrier to disease and to increase the general sense of well-being.

★★★ Adexolin concentrates of A and D are of such potency that the smallest prophylactic dose or the largest dose for "massive" vitamin therapy may be given with equal convenience. Each gm. capsule contains 6,000 international units of vitamin A and 1,000 of D (the equivalent in both vitamins of three teaspoonfuls of medicinal cod-liver oil). Each cc. of tasteless Adexolin Liquid contains 12,000 international units of A and 2,000 of D.

CAPSULES: Boxes of 25, 2/6; 100, 7/6; 500, 30/6; 1,000, 56/-; **LIQUID:** 4 oz. phials, 2/6; 2 oz. bottles, 7/6; 4 oz., 12/6; 8 oz., 22/6. The above prices, which are subject to the usual professional discount, do not apply in I.F.S.).

DIETARY DEFICIENCIES

AND THEIR TREATMENT

It is widely recognised that the diet of children of school age is in general by no means complete; but that the deficiencies are of a multiple nature is not so fully appreciated.

An investigation recently published in the medical press* has shown the extent to which supplements designed to counteract such deficiencies assist growth. 864 children from schools in the North and South of England were given in turn, as additions to their ordinary home diet, either milk, or cod liver oil and malt extract B.P., or Virol, or else no supplement. Each supplement was given for one term to three-quarters (648) of the children. The daily quantities given were of equal calorific value, and the experiment lasted for one school year. The following diagrams show the additional gains in weight and height of the treated children over the controls—

The superiority of the results obtained with Virol is at once evident, and demonstrates how the correction of multiple dietary deficiencies can be achieved by the use of a physiologically balanced preparation. Judged by the standard of so good a food as milk, the excellence of Virol is all the more striking. In all those children whose multiple dietary deficiencies need correction, Virol will evoke a maximum response. Only by giving a *complete* supplement is it possible to ensure this result.

* The "Medical Press & Circular," 27th October, 1937. A reprint of the article will gladly be sent on application to Virol Ltd., Harger Lane, Ealing, W.5.

STATUARY © 1127

During the six years since its introduction, Nembutal has been the subject of more than two hundred reports and references in medical literature. This record is important not only as an indication of the profession's interest, but also as evidence of the extensive clinical investigation to which the drug has been subjected.

• Today, its uses and advantages as well as its limitations are well understood, and the practitioner can make use of Nembutal with full confidence in its safety when administered as recommended. • Used orally, rectally or, in emergencies, intravenously, Nembutal exerts an extremely rapid but brief hypnotic and a pronounced sedative action from a dosage only about one-half that of most other powerful barbiturates. This small dosage, by lessening the amount of the drug to be eliminated, makes Nembutal, clinically, one of the safest

of the barbiturates. • Safety, rapidity and brevity of action recommend Nembutal for use as a pre-anæsthetic sedative in both major and minor surgery, as well as for the treatment of insomnia, hysteria, sea-sickness, nausea from any cause, eclampsia, delirium tremens, convulsions from strychnine or other poisoning, as a supplement to morphine in controlling the pain of early cancer and in obstetrics. • Nembutal is available in

a wide variety of forms, the most widely employed of which are the 1/2-grain and 1 1/2-grain capsules for oral administration. Comprehensive literature, together with a free trial sample of the 1 1/2-grain Nembutal capsules, will be sent upon request.

ANGINA OF EFFORT: A CLINICAL STUDY

BY

GEOFFREY BOURNE, M.D., F.R.C.P.

AND

R. BODLEY SCOTT, M.A., D.M., M.R.C.P.

(From the Cardiographic Department, St. Bartholomew's Hospital)

The clinical differences between the types of cardiac pain have been described in a previous paper (Bourne, 1935) and have also been stressed in a later one, "Angina Innocens: A Clinical Study" (Bourne, 1937). The present communication is a full analysis of a series of 112 patients suffering from the symptom of angina of effort. The method of presentation of these papers dealing with the various types of cardiac pain might suggest that an attempt was being made to describe individual diseases. This is by no means the case, but the definite clinical pictures provided by the different varieties of cardiac pain are so clear and distinct that it is believed that the mechanisms vary in each individual type of pain. Since at the moment it is quite impossible to determine minor and transitory changes in the coronary circulation by any other means, a careful scrutiny of the symptomatology is an essential method of approach to the problem. There are several possible organic causes of the symptom of angina of effort, presupposing this symptom to be the result of interference with coronary flow during exercise: coronary atheroma and syphilis of the aorta interfering with coronary flow are the commonest causes. Furthermore, cases have been described where severe anaemia was associated with angina of effort and where no evidence of cardiovascular disease was found at necropsy. (Cabot, 1926; Willis and Giffin, 1927; Elliott, 1934.)

The large majority of the patients here described were presumably suffering from coronary atheroma; seven had syphilitic aortitis, and one of these also had hypertension; one patient showed Addisonian anaemia as the only abnormality; and two had severe hypochromic anaemia; one of the last two, who in addition had aortic stenosis, lost his pain when the anaemia had responded to treatment.

Definition and Symptomatology

By angina of effort is meant a cardiac pain generally arising centrally or to the left of the sternum, sometimes radiating to one or both arms, which has an exactly quantitative relation to exertion. In a given case a given

* Since the publication of the above paper a certain amount of criticism of this label has arisen. Such criticism, as in the case of "pseudo-angina" and "secondary angina," has been entirely destructive. It is clear that the syndrome needs a definite name in order to stimulate an accurate inquiry into the signs and symptoms present in any individual patient. It is therefore in the hope that some better nomenclature may arise, and in the absence of any better term, that the name "angina innocens" is maintained.

amount of exertion will produce the pain, and cessation of that exertion will be followed immediately by a progressive diminution in and the disappearance of the pain. The pain never comes on at rest, except for the following exception. In a few cases, as in 10.7 per cent. of the present series, severe emotion may produce some pain; and since such emotion is associated physiologically with an increase in the heart rate and a raised blood pressure, it would be curious if in cases of angina of effort pain did not occasionally appear under these circumstances also. The effect of emotion in patients with angina of effort, however, is subsidiary in point of degree. The patient does not spontaneously complain that emotion produces the pain: it is only in response to a leading question that this is discovered. The outstanding symptom is pain which accompanies physical exertion, quantitatively, and which disappears with rest. The series here described is one consisting of cases of pure angina of effort; this fact is stressed because in any large consecutive series of cases of cardiac pain mixtures of the types of pain are not infrequent—for example, spasmodic angina is nearly always superimposed on an angina of effort, angina of effort is frequently complicated by coronary thrombosis, and the angina innocens type of pain has been observed to follow a coronary thrombosis. The various clinical pictures, however, are definite and distinct. *Provided a careful history is taken*, confusion between the different types of pain should not occur.

Reasons for Analysis

The chief reasons for analysing carefully a group of patients suffering purely from angina of effort are: first, that the different history from that given by patients with spasmodic angina suggests the presence of a different mechanism of pain production; secondly, that many patients are met with who have a history of pure angina of effort, and it is therefore helpful, so far as prognosis is concerned, to determine the expectation of life in a fairly large group of patients with an uncomplicated history of this definite symptom; thirdly, that with the introduction of new methods of treatment an accurate classification of clinical material is likely to be helpful in more accurately gauging the results of such treatment.

Exercise or physical effort produces different effects on the different types of cardiac pain. In the case of angina of effort this has already been described. An attack of

'I-so-gel' GRANULES

Indicated in
CHRONIC CONSTIPATION, COLITIS,
and allied gastro-intestinal disorders

"I-so-gel" is a natural vegetable material. The granules absorb many times their volume of water and swell into a firm, gelatinous mass which both stimulates natural intestinal movements and soothes inflamed intestinal mucous membrane. Indicated in chronic constipation, hæmorrhoids, colitis, dysentery, and allied gastro-intestinal disorders, and after colostomy. Action purely mechanical. Sugar-free. Ideal for diabetics.

In bottles at 3/- and 5/6 each

Descriptive literature sent post free on application.

Telephone: 3201 Bishopsgate (12 lines) **Allen & Hanburys Ltd., London, E. 2** Telegrams: "Greenburys Beth London"

was carefully investigated by cholecystography in all patients showing symptoms giving rise to suspicion of this condition. Cholecystitis was suspected in five patients, and was proved to be present in three cases. Among the other pathological states occurring in these patients the most striking is hemiplegia, which was found in three cases. Herpes zoster had occurred in three cases also.

An attempt was made to divide off the patients according to the physical and mental stress of their professions in order to determine the effect of this upon the presence of angina of effort. The mode of life was physically strenuous in thirty-two, or 28 per cent.; was physically and mentally strenuous in fourteen, or 12 per cent.; was mentally strenuous alone in forty-one, or 36 per cent.; or not strenuous physically or mentally in twenty, or 18 per cent. In 6 per cent. of cases there is insufficient evidence in the notes to come to an opinion on this point.

The Pain of Angina of Effort

The site of origin of the pain was worked out independently in the private group by G. B. and in the hospital group by R. B. S.; the results in each group are strikingly similar. The pain was central in 70.1 per cent. of the hospital cases and in 70 per cent. of the private cases. It arose in the left chest in 17.4 per cent. of the hospital cases and in 17.6 per cent. of the private cases. When angina of effort arises in the left chest it tends to appear in the upper rather than the lower half and does not start from the region of the heart's apex; these are minor distinctions between the left-sided pain of angina of effort and the left-sided pain of angina innocens. It started in the right chest in 4.4 per cent. of the hospital cases and in 4.7 per cent. of the private cases. The origin was epigastric in 4.4 per cent. of the hospital cases and in 2.3 per cent. of the private cases. It started in the left hypochondrium in one case, and in the left arm in two cases. Radiation was not invariable, as the pain remained localized to the site of origin in thirty-eight cases. When radiation occurred it was most frequent to the left arm; it sometimes occurred to both arms and less frequently to the right arm alone. Radiation to the abdomen and to the throat also occurred.

The association of the pain of angina of effort with other symptoms is shown in Table II. The accentuation

TABLE II.—*The Association of Angina of Effort Pain with Other Symptoms*

	Private Cases		St. Bart's		Total	%

Patients with dyspnoea. (Total number)	9	21.0	30	44.0	39	34.5
Patients with dyspnoea in whom food did not affect the anginal pain	6	14.0	14	20.3	20	17.5

of the pain if exercise is taken following a meal is clearly shown, but the effect of cold is less marked than in spasmodic angina. In some patients the severity of

the true angina of effort pain following a meal is so extreme that almost invariably in the case of the patient, and sometimes in the case of his medical attendant, it is thought to be due exclusively to some form of dyspepsia. The effect of food physiologically is to produce splanchnic congestion and systemic ischaemia, to increase the forcefulness of cardiac contraction, and to produce changes in visceral nervous tone. It is thus easy to account for the exacerbation of effort pain after food in patients suffering from angina of effort. The ability of certain patients to "walk off" the pain, or as in one case to work it off by the use of a heavy hammer, was originally noticed by Heberden, one of whose patients wrote him a letter describing accurately this peculiarity (Heberden, 1785). The fear of impending death, which is such a dramatic characteristic of the typical attack of spasmodic angina, has not been met with at all in the present series of cases of angina of effort. The explanation is probably that in this condition relief from the pain can be obtained immediately by ceasing the effort which is producing it. The patient thus does not push himself to a point where a pain is at all severe. In spasmodic angina, where the attack has to run its course, however slight the causative stimulus may have been, the patient feels helpless in the presence of the attack, which as it were gets out of hand. In these circumstances a sensation of impending death is easily understandable.

Other Cardiovascular Symptoms

Orthopnoea was present in 31 per cent. of the cases and paroxysmal dyspnoea in 4.5 per cent., but slight exhaustion was frequent, as it occurred in 52 per cent. Exhaustion of a severe type was complained of in only 5.4 per cent. Giddiness was fairly common, as would be expected in patients with vascular disease; giddiness on rising was present in 15.8 per cent., and giddiness at other times in 24 per cent. Fainting occurred in only two cases, one of these having aortic regurgitation.

Incidence of Cardiovascular Disease in Angina of Effort

Of the 112 patients, six died suddenly and unexpectedly; two died with the classical symptoms of acute left ventricular failure: twenty-eight suffered from a coronary thrombosis, proved electrocardiographically or giving a typical history; four suffered from aortic stenosis and three from aortic regurgitation; four had a proved active syphilitic aortitis; four had a systolic murmur at the aortic base, together with an enlarged heart as proved radiologically; one had a harsh systolic murmur typical of mitral regurgitation, with a systolic thrill at the apex, and with hyperpnoea; four had bundle-branch defects, shown electrocardiographically; five had inversion of the T wave in Lead I or II or both; two had PR intervals greater than 0.2 of a second; fourteen had hyperpnoea together with enlargement of the heart, as shown radiographically; seventeen had enlargement of the heart, proved by radiograph, with a normal blood pressure; and five had hyperpnoea without evidence of cardiac enlargement. This leaves a group of thirteen, or 11.6 per cent., in whom no evidence of cardiovascular disease was discovered. It is apparent that 88.4 per cent. provided unquestionable evidence of chronic cardiovascular disease.

It must, however, be remembered that a heart may appear normal clinically, electrocardiographically, and by x-ray examination, and may yet have an advanced degree of coronary disease (Bourne, 1936). A further point to be remembered is that interference with coronary

spasmodic angina is often initiated by exercise, but on the cessation of exercise a spasmodic attack continues or becomes even more severe; it "has to run its course." In the case of angina innocens (Bourne, 1937) it is often inaccurately stated by the patient that exercise brings on the pain, but further careful analysis of the symptom makes it clear that the pain is worse after rather than during exercise, and is continued for a long period while the patient is at rest. Coronary thrombosis occasionally manifests itself, if the thrombosis is a small one, by an angina of effort type of pain; but in contradistinction to the cases without thrombosis the onset is sudden, and after some days the pain generally becomes considerably less severe, and frequently disappears; the suddenness of the onset, the early severity, and the progressive improvement are characteristic of this latter clinical type.

Angina of effort, on logical grounds, would appear to be the type of pain most likely to be associated with a chronic organic lesion interfering with the coronary circulation. This probability seems to be borne out by the analysis of the present series of cases.

Historical

The relation between exercise and anginal pain has been recognized since the days of Heberden, and the probable relation between this type of pain and disease of the coronary vessels has been suspected since the observations of Jenner. There appears, however, to be no clinical study restricted to cases which show this pure exercise type of pain only. The historical steps subsequent to the writings of Heberden, Jenner, and Parry have been traced in Lewis's paper (Lewis, 1932), which also describes a series of experiments on the rhythmic and repeated muscular contractions in an arm whose blood supply was periodically occluded by a sphygmomanometer band. Lewis's main conclusions are that the pain produced in the muscle under these conditions is not due to the presence of arterial spasm and that it is not a direct result of lack of oxygen. He believes that the "pain is due to a stimulus arising directly or indirectly out of the contraction process," and that some chemical or physico-chemical agency is present as a causative factor within the muscle mass. Further, he concluded that this factor acts in tissue spaces though it is dependent on processes occurring within the muscle fibre as a result of its contraction. He believes that the pain is due to the accumulation of the factor in the tissue spaces, this accumulation being assisted if the blood flow through the spaces is lessened, and prevented if the blood flow is adequate. The condition in the heart whose circulation is impaired during exercise is probably closely analogous to that present in the muscles of the arm when these are exercised during a period of ischaemia.

Clinical Material

The clinical material of our series consists of 112 cases, forty-three seen in private practice and sixty-nine in the cardiac follow-up department of St. Bartholomew's Hospital. Of these, ninety-eight, or 88 per cent., were men, and fourteen, or 12 per cent., were women. In the private group there were three women, or 7 per cent., and in the hospital group eleven women, or 16 per cent. The age incidence is shown in the following table, the most striking fact perhaps being the earlier incidence of the syndrome in hospital cases. This may be explained by one of two factors—either that worry is more severe or that atheromatous changes are more common in the latter class.

TABLE I.—Age Incidence

Age	Private	Hospital	Total
30-39	0	4	4
40-49	4	14	18
50-59	15	22	37
60-69	17	24	41
70-79	7	5	12

Methods of Examination

In all cases a full history was taken. In the past history the following points were specifically investigated: rheumatic fever, growing pains, chorea, scarlet fever, tonsillitis, diphtheria, syphilis, and the history of the puerperium. Note was also taken of other diseases or surgical operation. A history of previous mental stress or trouble was not inquired into in every case. The following symptoms were investigated in each patient: pain, dyspnoea, sighing, orthopnoea, feeling of constriction, palpitation, exhaustion, cough, giddiness, dyspepsia, state of the bowels, catamenia, frequency of micturition. With regard to the pain the points elicited were: its character, position, radiation, duration, relation to exercise and emotion. The patients were asked whether the pain occurred during exercise, in a quantitative manner, or whether it would be worse when the exercise had been finished; also whether it was ever evident when they were resting or in bed. Inquiry was made about their present and past work, their ability to play games, to walk (with special reference to hills), to climb stairs, and to run; and also the quality of their sleep and their habits as regards smoking and alcohol.

Physical examination included special notice of the presence of dyspnoea, orthopnoea, cyanosis, pallor, pulsation, clubbing of the fingers, and tremor; the pulse rate; the state of the peripheral arteries and veins. The heart was examined by inspection, palpation of the apex beat, palpation of the praecordium for abnormal impulse or thrills; the position of the apex beat, the area of cardiac dullness, and the sounds were noted. Precordial hyperaesthesia was tested for in every case and the lungs and abdomen examined. An electrocardiogram was taken, and in some cases repeated. The Wassermann test was done. A six-foot film of the heart was taken, the contour of the heart noted, and the heart-chest ratio measured. In the private cases, however, a Wassermann reaction was only done if syphilis was definitely suspected, and an x-ray examination was not made in all cases.

Aetiology

The following were the chief points which emerged in considering the previous history of these patients. There was a history of rheumatic fever or chorea in ten, or 8.9 per cent. A history of syphilis was present in sixteen, or 14.3 per cent.; of these sixteen cases five gave a positive history of previous infection, the Wassermann reaction being negative, and seven had at the time of examination clinical evidence of a syphilitic aortitis with a positive Wassermann reaction. Syphilis and rheumatism were both somewhat commoner in the hospital group. A history of malaria was present in nine, or 8 per cent. Nine patients, or 8 per cent., had diabetes mellitus. One patient was suffering from pernicious anaemia, and two from idiopathic hypochromic anaemia; in all three cases successful treatment of the anaemia removed the cardiac pain. The state of the gall-bladder

remain up and about, later in the day. Of the twenty-five deaths four were from non-cardiac causes, in five the cause was unknown, and sixteen resulted from cardiac causes.

These conclusions would seem to indicate that "angina pectoris"—to use the inaccurate and general label—is not a dangerous symptom; for death does not occur during the attack of pain, and except in so far as it is the manifestation of a terminal coronary thrombosis the pain itself is not the fatal condition it is so commonly thought to be. This being so, it is the duty of the medical profession to discard the attitude of terror and taboo which is still so prevalent when dealing with and discussing this symptom, and to teach the general public that "angina" is in most cases not a dangerous or fatal condition; that, on the contrary, it is compatible with many years of useful life and is amenable to treatment; that danger is only to be feared from the underlying vascular disease.

Factors Influencing Prognosis

It can be said at once that the numbers in this series are too small for any accurate statistical analysis, but the following facts appear to emerge. Cardiac asthma, as would be expected, is a dangerous symptom, for all three patients died within two years. Abnormalities in the T wave of the electrocardiogram in Leads I and II seemed to be the next most serious finding. Seven out of ten patients in whom the T wave was inverted in Lead I or Lead II, or both, died, and two out of three patients died in whom the T wave was diphasic in Lead I or II. Thus nine out of thirteen patients with abnormalities of the T wave in Leads I and II died. This abnormality was not the transient electrocardiographic change of coronary thrombosis, but was persistent and permanent. Dyspnoea on exercise of a moderate degree was not more common in patients who subsequently died; not enough evidence was obtained that the presence, the absence, or the degree of dyspnoea resulting from exercise was helpful in prognosis. Coronary thrombosis is obviously likely to be a common cause of death in this group; but it is remarkable that the twelve patients in whom angina of effort started with a coronary thrombosis all remain alive. Active syphilis produced death in two cases out of eight; a third syphilitic patient died, but with coronary thrombosis in an atheromatous vessel. Diabetes appeared to make no difference to the prognosis.

It would thus seem that the cardiac prognosis ultimately depends upon whether or not a fatal coronary thrombosis is likely to develop, and upon the state of the left ventricular muscle. The only safe guide to determining this second point would be the amount of exercise that such a patient can undertake. This is of course generally restricted by the exercise pain. Some patients, however, can on some days undergo far more exertion without suffering pain than they can on others, and in these circumstances ability to climb hills or to walk reasonably well during a painless period is the most valuable prognostic point obtainable. Other complications of vascular disease, such as cerebral thrombosis, may prove fatal; this occurred in four cases in the present series.

Conclusions

1. Angina of effort is a clear-cut and definite symptom.
2. Angina of effort is associated in a very high percentage of cases with provable organic cardiovascular disease.

3. In our opinion, taking into account the impossibility in some cases of proving during life that coronary disease exists, angina of effort does not occur without coronary disease, except possibly in some cases of severe anaemia.

4. This coronary disease may be severe or slight, and probably in the majority of cases does not cause obstruction to the blood flow in the resting heart, but produces its effect by interfering with the normal stretching of the coronary arteries which occurs during exertion.

5. Angina of effort is in itself not a dangerous symptom: patients do not die in an attack. Danger is only to be apprehended from the occasional occurrence of coronary thrombosis, from the results of coronary atheroma on the ventricular muscle, or from other vascular accidents.

THE SHORTAGE OF CALCIUM IN THE "POORER-CLASS" DIET

BY

KATHARINE H. COWARD, D.Sc.Lond.

ELSIE W. KASSNER, F.I.C.

AND

LETTITIA W. WALLER

(From the College of the Pharmaceutical Society, London)

Certain routine tests carried out in this laboratory gave results which emphasized the fact that the ordinary diet of the poorer classes, consisting largely of bread, margarine, jam, potatoes, some meat, and a little milk and fresh vegetables, might be seriously deficient in bone-forming elements. An experiment designed to test this point has amply confirmed the suspicion.

Simpson and Wood (1935) investigated the influence of supplements of (a) cod-liver oil, (b) halibut-liver oil plus dried milk, and (c) virol to the diet of children attending various infant welfare centres in a typical London area. The children were mostly from working-class homes, and their diet was not controlled by the investigators. The doses of the three supplements were adjusted so that each child received an additional 75 calories a day. The amount of vitamin D received daily as cod-liver oil by each child was 2,080 international units, contained in 8 grammes of oil, which was therefore a very rich sample. (The *British Pharmacopoeia* 1937 Addendum requires a minimum vitamin D content of 85 international units per gramme.) The dose of halibut-liver oil gave approximately three and a half times as much vitamin A (as judged by "blue units") and a quarter as much vitamin D as the dose of cod-liver oil. Since the daily dose of halibut-liver oil was only 0.2 gramme, an extra half-ounce of dried milk was given to bring the calorie value of the total supplement up to that of the cod-liver oil supplement. The daily dose of virol was 20 grammes, stated to have a

flow may only be relative. Coronary ischaemia may occur either because there is a narrowing of some part of the coronary circulation or because there may be at some point in the coronary circulation an area of slight disease which produces loss of elasticity of the vessel. Under this latter condition the coronary flow would be normal except during such a state of exercise as would require a greater flow of blood than the inelastic vessel could provide. The cardiac nutrition would not suffer under these circumstances, but pain of a typical effort character would result from the relative cardiac ischaemia produced during exertion. The presence or the degree of pain depends also on other factors, such as possibly the psychological state of the patient (Bourne, Scott, and Wittkower, 1937; Wittkower, 1937), or on the degree of sensitiveness of the nervous system.

Three negative points are worthy of notice. In the above list of cardiovascular conditions there is no case of congestive failure, no case of auricular fibrillation, and only one of mitral disease, this being a case of mitral regurgitation. Mitral stenosis is conspicuously absent.

Relation between Angina of Effort and Coronary Thrombosis

The estimation of the incidence of coronary thrombosis in a series of cases depends, first, upon the proof of the condition electrocardiographically, and, secondly, on the presence of a typical history of an attack. We did not regard the latter point as positive unless the patient had suffered from a severe attack of precordial pain, so acute as to be incapacitating and lasting continuously or intermittently over a number of days. In many cases there was a history that the pain needed relief by an injection of morphine, and in most of them there was evidence that such an attack was followed by a diminution in the patient's powers of physical activity. Wherever an attack of this nature had been sufficiently recent the correctness of the diagnosis was confirmed by the fact that changes were still occurring in the electrocardiographic tracings.

Coronary thrombosis might initiate the patient's period of ill-health, might occur as an incident during its course, or might be the terminating event of the illness. Coronary thrombosis was proved to have initiated the condition in two cases, and a typical history suggesting that it had done so was present in fifteen others; it was proved to have occurred in two cases during the course of the illness; and a typical history of coronary thrombosis was present in ten others, also, during the course of the illness. Coronary thrombosis was proved to have terminated the illness in two cases, and probably did so in one other. The total number of patients having a coronary thrombosis at some time during the illness was thirty-two, or 28.6 per cent.; the number having more than one coronary thrombosis was five, or 4.5 per cent.

The clinical history of angina of effort, in so far as this condition is related to coronary thrombosis, may be of one of three types. A coronary thrombosis may occur and may be followed directly by angina of effort, which may subside, with complete recovery from cardiac pain; alternatively, the angina of effort may be persistent. Another train of events may be as follows. A coronary thrombosis is succeeded by angina of effort which disappears, but a subsequent attack of illness of another type—for instance, influenza—may result in a recrudescence of the angina of effort symptoms. In other cases coronary thrombosis may be followed by angina of effort which, although it improves very gradually up to a point, never completely disappears.

Prognosis

The death rate of the whole group was 22 per cent.; in the private cases this was 28 per cent. and in the hospital cases 19 per cent. Table III and the chart give the

TABLE III

Years ..	0-1	1-2	2-3	3-4	4-5	5-6	6-7	7-8	8-9	9-10	11-12	14-15	19-20	Totals
Alive ..	24	19	14	8	6	7	2	2	1	2	1	1	1	58
Dead ..	6	10	2	2	3	0	0	1	0	0	0	0	0	24
Total ..	30	29	16	10	9	7	2	3	1	2	1	1	1	112

number of years between the first onset of the symptoms and the date on which the patient died or was last seen; the chart thus shows graphically the length of life either

Chart showing the number of years from the onset of the symptoms to the date on which the patient died or was last seen. Shaded areas = patients alive; black areas = patients dead.

from the first onset of angina of effort or from the onset of a coronary thrombosis which was followed by a period of angina of effort; in two of the patients giving the latter history the pain cleared up completely. Since the history only extends up to a period of two years in a large number of cases it is clear that the data as regards duration of life are not complete. But it is equally evident, taking into account the age of the patients, as shown in Table I, and considering this in relation to the survival figures, that the survival rate is not far short of that which would be expected for patients of that age without angina of effort but with evidence of cardiovascular disease. The death rate is: for the first year 20 per cent., for the second 35 per cent., for the third 12 per cent., for the fourth 20 per cent., for the fifth 33 per cent., for the sixth and seventh nil, and for the eighth 33 per cent. The series is, of course, too small for any definite conclusion to be drawn, but the figures appear to indicate that the chance of death is more or less the same for a patient with angina of effort during each of the first five years. A point that needs to be stressed is that death in an attack of angina of effort is not recorded in the present series, and it would therefore seem that angina of effort is of itself not a dangerous symptom, but that it is an indication of a greater or lesser degree of coronary disease. Only one patient died in pain, and a careful history of the attack, taken from an intelligent friend who was with him throughout, leaves little doubt that this patient had been seized with a coronary thrombosis early in the morning, and that death occurred while he was endeavouring to

doses of both cod-liver and halibut-liver oils were so high that they must have contained abundance of vitamins A and D to satisfy the rats' needs.

Result of First Experiment

(a) Increase in Weight.—The effect on the weights of the rats may be seen in the accompanying chart of the

Chart showing the effect of giving (a) no supplement, (b) cod-liver oil, (c) halibut-liver oil plus dried milk, (d) virol on the increase in weight of rats fed on a diet as much as possible like that of the poorer classes. The three supplements are of equal caloric value.

growth curves. The variation between the rats of any one group is not great. The results are summarized in Table II. The average increase in weight of the control

TABLE II.—Average Increase in Weight in Six Weeks of Four Groups of Rats Given a Mixed "Poorer-class" Diet, with Supplements in Three of the Groups

	Average Increase in Weight in Six Weeks (grammes)		Average Increase in Weight of Males and Females (grammes)
	Males	Females	
Group 1 (No supplement)	43.7	42.2	42.95
" 2 (+ Cod-liver oil)	69.7	65.6	67.65
" 3 (+ Halibut-liver oil and milk)	84.3	73.6	78.95
" 4 (+ Virol)	42.7	48.8	45.75

rats given the "poorer-class" diet only was 42.95 grammes in six weeks; that of the rats receiving the cod-liver oil supplement was 67.65 grammes; and that of the rats given the halibut-liver oil plus dried milk was

78.95-grammes—clear evidence of the lack in this diet of factors (for example, vitamins A and D) which can be supplied by cod-liver oil and by halibut-liver oil plus a little dried milk. On the other hand the increase in weight of the rats given the supplement of virol was 45.75 grammes, which was only slightly, certainly not significantly, greater than that of the rats receiving no supplement. We have completely failed to reproduce in rats the effect which Simpson and Wood obtained on children and to discover what determined the effect.

(b) Further Comparison of the Supplements by a Different Criterion—"Ash Content of the Bones."—Before the termination of the experiment we decided to compare the four groups of rats by another criterion—namely, the ash content of the bones—to see whether some constituent of the virol might have had an effect on calcification which could not be brought about by vitamin therapy alone. Accordingly, the percentage of ash of the dry extracted bone (one femur and one humerus, separately, of each rat) was determined in four rats in each group. The result may be seen in Table III.

TABLE III.—The Percentage of Ash in the Dry Extracted Bone (Femur and Humerus) of Four Rats of Each of the Groups 1, 2, 3, and 4

Group	Supplement	Litter	Rat	Ash in Dry Extracted Bone	Average Ash Content
1	None	6472	9308 (M)	F 43.31 H 40.28	40.19
			9334 (M)	F 38.07 H 38.73	
			9317 (F)	F 37.34 H 39.44	
			9342 (F)	F 42.85 H 41.18	
2	Cod-liver oil	6472	9306 (M)	F 36.69 H 36.62	37.59
			9332 (M)	F 35.77 H 37.54	
			9315 (F)	F 36.12 H 40.14	
			9340 (F)	F 37.90 H 39.96	
3	Halibut-liver oil + milk	6472	9305 (M)	F 39.38 H 38.89	39.48
			9331 (M)	F 38.75 H 38.58	
			9314 (F)	F 41.05 H 39.83	
			9339 (F)	F 40.72 H 38.65	
4	Virol	6472	9307 (M)	F 36.97 H 39.22	38.70
			9333 (M)	F 35.78 H 38.09	
			9316 (F)	F 40.10 H 42.92	
			9341 (F)	F 38.28 H 38.26	

There is no significant difference between the average ash contents of the four groups, and they are all very much below the normal (which is 50 to 55 per cent.) for rats of their age and weight, although two groups at least received abundance of vitamin D. It seems highly probable, therefore, that none of the rats received enough calcium or phosphorus, or both, for normal calcification to take place. This was an alarming possibility. It has been generally recognized that the value of fresh milk as a food is partly due to its calcium and phosphorus content; but it had not seemed possible to us that the ordinary mixed poorer-class diet could be so seriously deficient in these elements as to reduce the percentage of ash in the bones of growing rats from 55 to 40 per cent. in six weeks. Another experiment was therefore carried out to determine whether it really was a shortage of calcium and phosphorus in the diet that had led to the low calcification.

calorie value of 74. Its vitamin content was said to be not so high as that of the doses of cod-liver oil or halibut-liver oil, but "sufficient to obviate the possibility of a complete lack of vitamins in the basic diet." Its special value as a supplement was thought to be due to its balance of protein, fat, and carbohydrate. The result of this investigation, stated briefly, may be said to show that the giving of cod-liver oil or of halibut-liver oil plus milk was beneficial, but that virol was more beneficial still. An elaborate statistical examination of the results showed that the observed differences might be considered significant.

The question that interested us was what might be the deficiency in the children's diet that was being made good by the addition of 20 grammes of virol a day. It seemed scarcely possible that about three-quarters of an ounce of a "well-balanced" food could seriously affect the increase in weight of a child. Moreover, when the 22.4 per cent. of volatile matter, probably mostly water, was allowed for, it left only 16.52 grammes of well-balanced food—very little more than the half-ounce (14.17 grammes) of dried milk which had not had a beneficial effect, although milk must surely be one of the best-balanced foods known. This, then, did not appear to account for the result obtained.

An examination of the published list of contents of virol—namely, marrow fat, glycerin, extract of red bone marrow, eggs, salts of calcium, iron, etc., malt extract, and the juice of fresh lemons—suggested that the vitamin B it contained might be high enough to produce beneficial effects when the basic diet was low in these factors. A biological determination of the vitamin B₁ value of a sample of virol purchased in the open market was made in this laboratory. It was found to be 0.7 international unit per gramme. Thus the daily dose of virol given to each child contained about 14 international units, and since a child of 4 years requires about 55 international units of vitamin B₁ a day, this cannot be considered a very large contribution to its needs. Moreover, the supplement of dried milk would contain 6 to 9 units of vitamin B₁, if none had been lost in the drying. It is unlikely that modern methods of drying milk would reduce the vitamin B₁ potency much, and it was concluded from these calculations that it was probably not the presence of vitamin B₁ in the virol that accounted for its beneficial effect on the children.

First General Nutrition Experiment on Rats

It was therefore decided to repeat the whole experiment on rats as it had been carried out on the children. Four groups of eight rats each were used, to correspond to the four groups of children. Litters of four or eight rats were divided among the groups so that each litter was represented equally in each group, which comprised three male and five female rats. Each rat was kept in a separate cage throughout the experiment, and the cage was provided with a grid so that the animal had no access to faeces. Fresh tap-water of the Bloomsbury district was supplied daily.

The experiment was carried on for six weeks. Throughout that time the rats were weighed twice a week. The diet given to all the rats was chosen so as to be as much like the diet of the poorer classes as possible. The scheme drawn up at the beginning and followed with almost no variation is given in Table I.

The groups of rats received supplements similar to those given to the groups of children—namely: Group 1, no supplement; Group 2, cod-liver oil; Group 3, halibut-

liver oil; Group 4, virol. The doses of cod-liver oil, halibut-liver oil, and virol respectively were determined from the following consideration. The calorie requirement of children from 2 to 3 years is 1,100 to 1,400; that of children of 3 to 6 is 1,400 to 1,700 (Ministry of Health Nutrition Report, 1934). If the average require-

ment of the children in the experiment was 1,500 calories, then the 75 calories given as a supplement would be one-twentieth of their daily needs.

A rat of 40 grammes weight requires 4 to 5 grammes dry weight of fat-free food a day. The rats' supplement for this experiment should supply one-twentieth of the calorie intake—that is, 1/20 of 20 calories, which is 1 calorie. The dose of cod-liver oil given to each child of Group 2 was 8 grammes; therefore the dose for each rat of Group 2 was 1/75 of this, which was 0.11 gramme. This would yield 1 calorie.

Similarly the dose of halibut-liver oil given to each child of Group 3 was 0.2 gramme, and therefore the dose for each rat of Group 3 would be 1/75 of 0.2 gramme, which was 0.0027 gramme. This would yield 0.025 calorie. Also 1/75 of 1/2 oz. of dried milk would be 1/75 of 14.17 grammes = 0.19 gramme—yielding about 1 calorie. The dose of oil was given as one drop of a dilution of halibut-liver oil (27 in 200) in olive oil. The dose of dried milk was weighed for each rat and given on a small dish, moistened with water. It was stated that 20 grammes of virol had a calorific value of 74, therefore 0.27 gramme of virol would have a calorific value of 1. This was given on a small dish. It was always taken readily.

It is recognized that giving supplements to experimental rats was not necessarily comparable to giving supplements to children, for it is possible that the children did not receive enough food (calories) for their needs, whereas the rats were given more food than they ate. Experiments on rats are almost always carried out in this way, for a rat eats only enough each day for its needs, the amount having often been shown, from records of food given and food left, to be fairly constant from day to day.

The cod-liver oil and halibut-liver oil used for the rats were as nearly as could be judged of the same vitamin A and D content as the oils used for the children. The vitamin D content of the oils used for the children was stated in international units, but the vitamin A value was only given in "blue units," and other oils with similar "blue value" cannot be regarded as having necessarily the same vitamin A values. Oils of nearly similar vitamin D and "blue" values were used for the rats, and the

would have produced the effect obtained. But it is very unlikely that our milk contained much less than 0.76 gramme of calcium per litre, since the average value is 1.12 grammes. Therefore it seems highly probable from this experiment that the calcium of milk is no more easily available to the rat than is the calcium of inorganic salts. This point will be investigated by direct experiment later.

Each day during the first and fifth weeks a typical ration for a rat was dried at 100° C. The seven weekly rations were bulked separately. The dry weight of the first week's ration was 100 grammes and of the fifth week's ration 85 grammes. As an excess of bread was given each day these amounts exceeded the quantity of food eaten by each rat daily. The first week's ration contained 40.5 mg. calcium and 157 mg. phosphorus. The fifth week's ration contained 26.2 mg. calcium and 165 mg. phosphorus. The averages of these—33.3 mg. Ca and 161 mg. P—may be taken as an approximation of the average weekly supply of calcium and phosphorus to each rat, and 4.8 mg. Ca and 23 mg. P as the average daily supply. The amounts eaten would be somewhat less than these, as a little white bread was always left. The London tap-water was found to contain 6.38 mg. calcium per 100 ml. Thus a rat drinking 15 c.cm. of water daily would obtain about 1 mg. Ca per day or 7 mg. per week from this source. The amounts of calcium received by the rats of the first four groups would then be:

Group	Mg. Calcium Received per Rat per Day from			
	(a) The Diet	(b) Tap-water	(c) Supplement	Total
1	4.8	1	0	5.8
2	4.8	1	1.95	7.75
3	4.8	1	5.85	11.65
4	4.8	1	17.55	23.35

Since the medium dose of calcium salts was not sufficient to bring about perfect calcification and the highest did so, the amount of calcium needed for perfect calcification must lie somewhere between the two. A curve relating the average ash content of the groups and the quantities of calcium received indicates that the amount of calcium required by the rat for perfect calcification is about 15 mg. a day, which is some two and a half times the amount that the rats received from their diet without any supplement.

Leitch (1937) in a long review on the determination of the calcium requirements of man has concluded that a child of 2 to 9 years needs 0.9 gramme of calcium per day. The amount obtained by a child from the diet described here may be estimated from the following consideration. Assuming the ratio of the calorie intake of the child to that of the young rat (as in this experiment) to be 75:1, as calculated in the early part of this paper, the child would receive 360 mg. of calcium per day from the diet, and, assuming he drank two pints of water a day, he would receive about 70 mg. of calcium from the water. This makes a total of 430 mg. of calcium actually received, and he needs 900 mg.

Summary

A comparison of (a) cod-liver oil, (b) halibut-liver oil plus dried milk, and (c) virol, given as supplements to different groups of young rats fed liberally with a mixed diet of white bread, potatoes, cabbage, margarine, jam, tea, a little butter, milk, brown bread, sausage, etc.,

Second General Nutrition Experiment on Rats

Six groups of eight rats (five males and three females), weighing about 40 grammes each, were fed for five weeks on the same diet as the rats in the first experiment, each rat being housed in a separate cage with a grid raised one inch above the floor. The same Bloomsbury tap-water was supplied daily. Each rat in every group was given six drops (approximately 0.12 gramme) of a good sample of cod-liver oil daily directly into its mouth. One group received no other supplement, three groups were given graded amounts of a mixture of salts containing calcium and phosphorus, and two groups had different amounts of milk.

The salt mixture was made up of the salts which contained calcium and phosphorus in Steenbock's salt mixture No. 40, in the proportion in which they occur there. It therefore consisted of:

	grammes
Dipotassium hydrogen phosphate, $\text{Na}_2\text{HPO}_4 \cdot 12\text{H}_2\text{O}$	35.8
Dipotassium hydrogen phosphate, K_2HPO_4	69.6
Calcium phosphate, $\text{Ca H}_2(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$	68.8
Calcium lactate, $\text{C}_3\text{H}_5\text{O}_2\text{Ca} \cdot 5\text{H}_2\text{O}$	15.4
	189.6

These salts constitute about 75 per cent. of Steenbock's salt mixture No. 40, and as this mixture furnishes abundance of calcium and phosphorus when supplied as 4 per cent. of the diet for vitamin A or B₁ tests, 3 per cent. of the new salt mixture should provide plenty of calcium and phosphorus when given to rats receiving a mixed diet. Assuming a young rat eats 5 to 6 grammes dry weight of food per day, he should be given 0.15 to 0.18 gramme of salt mixture to supply the necessary calcium and phosphorus. The salt mixture contains 9.5 per cent. calcium and 14.8 per cent. phosphorus; therefore 0.18 gramme of mixture would furnish 0.017 gramme calcium and 0.027 gramme phosphorus daily. The supplements given to the different groups of rats were thus:

- Group 1: No supplement.
- Group 2: 0.02 gramme salt mixture daily.
- Group 3: 0.06 gramme salt mixture daily.
- Group 4: 0.18 gramme salt mixture daily.
- Group 5: 5 ml. pasteurized milk daily.
- Group 6: Pasteurized milk *ad lib.* (average 13.6 ml. daily at the beginning of the experiment, up to 20 ml. later).

The doses of salt mixture were given in separate dishes, mixed with a little dextrin and moistened with water to prevent scattering. The rats took their portions readily. Group 1 received a similar amount of dextrin.

Result of Second Experiment

(a) *Increase in Weight.*—The effect of the supplements on the increase in weight of the groups of rats may be seen in Table IV. The groups were very small, consisting of five males and three females each, therefore slight differences in averages cannot be considered seriously. Thus the supplements of the salt mixture cannot be regarded as having had any influence on the increase in weight of the rats, but the milk supplements certainly had a beneficial effect. It is, of course, impossible to say which constituent of the milk it was that made good a deficiency in the mixed diet. It may have been the proteins of high biological value or some part of the vitamin B complex. It would not be the vitamin A or D content, as the rats were receiving so much of both of these factors in their doses of cod-liver oil that a little more could not have any effect. The mineral content of the milk will be considered in the next section of the results.

TABLE IV.—Average Increases in Weight of Groups of Rats (five male and three female) given a "Poorer-class" Diet plus a Liberal Dose of Cod-liver Oil Daily, and, in addition, Graded Doses of a Calcium-Phosphorus Salt Mixture or Graded Doses of Pasteurized Milk Respectively.

Group	Supplement	Average Increase in Weight in Five Weeks (grammes)		Average Increase in Weight of Males and Females (grammes)	
		Males (5)	Females (3)	Weighted Means	Means as if from Equal Number of Males and Females
1	None	52.0 (4 only)	47.3	50.0	49.65
2	0.02 gm. salt mixture	53.2	55.7	54.1	54.45
3	0.06 gm. " "	55.8	51.7	54.3	51.75
4	0.18 gm. " "	54.7	63.5 (2 only)	57.2	59.10
5	5.0 ml. milk	76.6	80.3	78.0	78.45
6	Milk <i>ad lib.</i> , average 13.6 ml. during the first three days; unmeasured later, but less than 20 ml.	120.0	80.3	105.1	100.05

(b) *Calcification of Bones.*—The percentage of ash in a dry fat-extracted femur and humerus of each rat was determined in the usual way. The results are shown in Table V.

It is quite evident that the mixed diet similar to that of the poorer classes is seriously deficient in calcium and phosphorus. The bones of the rats receiving the mixed diet plus liberal amounts of cod-liver oil contained only 39.70 per cent. of ash, which is similar to the results found in the first experiment. The addition of graded quantities of a mixture of salts containing calcium and phosphorus brought about increased calcification, the greater the dose of salt mixture given the greater being the calcification of the bones. The highest dose of salt mixture produced 52.12 per cent. of ash, which may be considered a normal amount for rats of their age.

The small dose of milk, 5 ml. daily, produced an ash content of 45.74 per cent., slightly less than that obtained from the addition of 0.06 gramme of the salt mixture. The high dose (20 ml. daily, of which 2 or 3 ml. was generally left) produced an ash content, 52.03, equal to that yielded by the highest dose, 0.18 gramme, of salt mixture. Unfortunately no determination of the calcium and phosphorus content of the milk given to the rats was made, but the following calculation leads to an instructive conclusion.

Apparently 5 ml. of the milk contained less calcium than 0.06 gramme of the salt mixture given. We may suppose that 5 ml. of the milk had as much calcium as 0.04 gramme of the salt mixture—that is, 0.0038 gramme. Therefore the milk apparently contained 0.76 gramme of calcium per litre. This result seems to have some bearing on the question of the availability of the calcium in milk. It is generally stated that milk owes a great part of its value as an antirachitic agent not merely to its high calcium content but to the fact that the calcium is present in a specially available form. Now the average calcium content of milk is 1.12 grammes per litre. The milk used in this experiment apparently contained 0.76 gramme per litre, judging from the effects produced on different groups of rats given 5 ml. of milk and known graded amounts of calcium respectively. Now, if the calcium of the milk were more easily available than the calcium of the salt mixture a smaller amount of calcium than 0.0038 gramme in 5 ml. of milk

on the morbid anatomy of the disease. Doubtless there is an inflammatory congestion of the mucosa of the colon, and the character of the symptoms suggests that this may be at its most severe in the lowest part of the intestine. The conspicuous presence of blood in the motions must indicate some degree of superficial ulceration of the mucosa, but the rapid recovery which ensues makes it clear that there can be no gross ulcerative changes.

Clinical Features

Describing first a typical case, the disease develops with great rapidity, with the onset of fever up to 102-3°, abdominal pain with colic and perhaps tenesmus, and purging. The stools are loose and contain obvious quantities of blood and mucus. Pus is also present on microscopical examination. The passage of blood and mucus without faecal material is exceptional, but may occur in between the typical actions. The bowels during the first twelve hours are moved perhaps every hour, or even more frequently. Abdominal pain may be severe, but is not excruciating as in intussusception. Vomiting may be absent throughout; but it is common at the early stage of the disease for some vomiting to occur with each action of the bowels, clearly due to the general intestinal turmoil going on. In exceptional cases (*vide infra*) vomiting is a prominent symptom. By the second day the more violent symptoms are subsiding, and by the end of the third day the temperature is falling rapidly, the blood is disappearing from the stools, pain is lessening and the number of stools is diminishing. The patient is left feeling considerably weakened by the attack. The constitutional disturbance seems to arise not so much from toxæmia as from dehydration, loss of sleep, and starvation. For the next few days some mild diarrhoea remains, the motions being unformed and showing the presence of some mucus; blood, however, is only now to be found by microscopical examination, and even this soon disappears. From this time onwards there is usually rapid recovery, so that by the end of about ten days from the onset the child is as well as before the attack.

In mild cases the symptoms are less severe and the motions, although containing mucus, may show no obvious blood; but on microscopical examination blood and pus cells are constantly to be seen. A similar condition of the stools may be found in cases convalescent from a typical attack, and in both these conditions there is considerable danger that the true nature of the disease may pass unrecognized.

In exceptional cases vomiting may apparently be troublesome, and R. E. Smith (1931) has raised the question whether there may not be a gastric type of Sonne infection. Further observations are required to settle this point, but it might well be kept in mind in connexion with epidemics of unexplained vomiting, especially in institutions.

Course and Prognosis

The usual short course of the disease has been described. Relapses within a week of recovery are occasionally seen. Complications and sequelae seem to be practically unknown. The length of time during which the stools may remain infectious has been discussed. Danger to life may arise in the case of weakly infants who acquire the disease; otherwise the infection appears to carry no death rate.

Diagnosis

The clinical diagnosis of Sonne dysentery is not difficult in typical cases. In infants and young children intussus-

ception must be considered. This is essentially an obstructive condition, whereas Sonne dysentery is a diarrhoeic disease and pus is present in the stools. Further, the positive points in favour of intussusception are absent in dysentery—namely, the characteristic temporary collapse with the crises of abdominal pain, the presence of a tumour felt through the abdominal wall or per rectum, and the diagnostic radiographic picture with an opaque enema. In older children and adults Sonne dysentery has to be distinguished from other forms of infective diarrhoea and food poisoning, and this rests upon the bacteriological examination of the stools. The danger of overlooking mild, convalescent, and atypical cases has been emphasized.

The bacteriological diagnosis of the disease is of the utmost importance, and a reliable report can be obtained in eighteen hours. A swab may be taken of the rectal mucosa, in which case the specimen must reach the bacteriologist with practically no delay; but usually a specimen of the faeces is submitted to examination. Here again it is important that the specimen should be as fresh as possible, and although it is difficult to lay down a precise rule I should not myself rely upon a negative report if the stool were twenty-four hours old before being planted out. In order to obtain as satisfactory and pure a growth of the bacillus as possible a piece of mucus is picked out of the stool, gently washed free of faecal material in normal saline, and spread by means of a swab over a small area of a warm dry plate of lactose-lime-bile-salt-agar or similar medium. Any surplus material is removed from the surface, and from this area, by means of a spreader, the rest of the plate is planted out by quartering. Eighteen hours later a suspicious colony is removed and emulsified in water on a slide. A loopful of Oxford specific agglutinating serum for the Sonne bacillus is added, and if the test is positive macroscopic clumping is seen within a minute. Confirmatory sugar reactions will take an additional twenty-four hours, but in expert hands the results of the Oxford serum tests seem entirely reliable. A similar technique with other types of Oxford sera leads to the recognition, if needed, of Flexner-group and Shiga dysentery, the typhoid and paratyphoid, Gaertner and *aertrycke* infections. Sero-diagnosis from the patient is not helpful, at all events in early stages of the disease.

Treatment

Sonne dysentery is a notifiable disease. Preventive measures to check its spread can hardly be relied upon to be completely successful. In the early and most contagious phase of the infection the patient may require attention every half-hour, and in practice it seems impossible to institute measures which will with certainty prevent the infection of other children in a ward. Where practicable, therefore, the patient should be isolated. When this cannot be done those in attendance on the patient must not handle other children, and in particular must have nothing to do with the preparation of their meals. To protect herself the nurse should wear surgical gloves. In houses the lavatory should not be used by infected people. It is customary to obtain three negative tests of the stools before regarding the case as free of infection.

Remedial treatment should be undertaken in the expectation that the worst of the disease will be over in three days. Thus the indications are to relieve pain and prevent dehydration. The customary anti-dysenteric treatment by repeated doses of sodium and magnesium sulphates does

failed to confirm the results obtained by Simpson and Wood (1935) in a similar experiment on children. As judged by the increase in weight of the rats, the cod-liver oil had a decidedly beneficial effect, the halibut-liver oil plus dried milk had a slightly better effect, whilst the wrol was almost without influence as compared with the control rats receiving no supplement. As judged by the percentage of the ash content of the bones of the rats, all three supplements were equally without effect. This suggested that the mixed diet was deficient in the elements required for calcification.

A second experiment was carried out on six groups of rats, all of which were fed liberally with the same mixed diet and given six drops each of a good sample of cod-liver oil daily—a very large dose for a rat. One group received no other supplement, three were given graded doses of a mixture of salts of calcium and phosphorus, and two had graded doses of milk.

The salt mixture had no significant influence on the increase in weight of the rats, but the doses of milk had a distinctly beneficial effect.

The graded doses of salt mixture produced graded results in the percentage of ash in the bones, ranging from 42.83 per cent. for the lowest dose (0.02 gramme) to 52.12 per cent. for the highest dose (0.18 gramme), which is about the normal percentage for rats such as these. The bones of the rats given no supplement contained 39.7 per cent. ash. This proves quite clearly that the ordinary mixed diet of the poorer classes is seriously deficient in the elements required for the calcification of bone.

The lower dose of milk, 5 ml., produced 45.74 per cent. of ash in the rats' bones; the higher dose, about 15 to 16 ml., produced 52.03 per cent. of ash. A comparison of the submaximal effects from the lower dose of milk and the lower doses of salt mixture showed that the milk apparently contained 0.76 gramme of calcium per litre. As this is less than the average calcium content (1.12 grammes per litre) of cows' milk it is concluded that the calcium of cows' milk is no more easily available for the rat than the calcium of inorganic salts.

The serious shortage of calcium in the mixed "poorer-class" diet was confirmed by analysis of typical bulked days' rations as given to the rat.

The Ministry of Labour has published new editions of pamphlets dealing with the Local Government Services and Social Work for Women, which are Nos. 21 and 22 in the Choice of Career Series. This series is compiled by arrangement between the Incorporated Associations of Headmasters and Headmistresses and the Ministry of Labour. The Local Government Service includes opportunities for those who qualify as accountant, architect, barrister, doctor, engineer, solicitor, surveyor, and teacher. The branches of social work include: hospital almoner, labour management, factory inspector, club leadership, occupational therapy, church work, policewoman, and probation officer. Full information is given of the nature of each type of work, the qualifications and training required, the cost of training, and the prospects of advancement. The pamphlets are on sale at H.M. Stationery Office and through any bookseller at the price of 4d. each (5d. post free).

SONNE DYSENTERY

BY

REGINALD MILLER, M.D., F.R.C.P.

Physician to St. Mary's Hospital and Paddington Green Children's Hospital

Although for some years Sonne dysentery has been known in paediatric circles as one of the bugbears of children's hospitals, there are many busy practitioners who have seen nothing of the disease and remain unfamiliar with its characteristics. In view of the present epidemic in London and the home counties a brief account of the disease may perhaps be considered opportune.

Bacillary dysentery may be described with sufficient accuracy as consisting of three types, due respectively to (a) the Shiga bacillus, (b) the Flexner group of bacilli, and (c) the Sonne bacillus. The differentiation of these three types is ultimately a bacteriological matter, but clinically there are important general differences between them. Shiga dysentery, the most serious and fatal type, is practically non-existent among the ordinary population of London, and probably of the country: in seventeen years no example of this infection has occurred at the Paddington Green Children's Hospital. Flexner-group dysentery, as compared with Sonne dysentery, is less common but more severe, prolonged, and dangerous. Sonne dysentery, with which we are here concerned, is therefore the commonest of the three types but runs the mildest and shortest course.

Epidemiological Features

Sonne dysentery, although probably commonest in the summer months, may occur at any time of the year. No age is exempt from it, and while it is most frequently seen in young subjects, infants do not seem to be preponderantly affected. In these two particulars it differs from the so-called epidemic gastro-enteritis, which is essentially a summer disease and strictly confined to infants.

The disease spreads with such ease and rapidity that it is tempting to think that transmission may be by airborne infection. There is, however, as yet no clear proof that transmission can occur by any means other than the ingestion of the specific bacillus, the ultimate source of which is the infectious faeces of the patient. Thus, as in typhoid fever, patients and those in attendance on them must be regarded as the source of contamination of food, drink, feeding utensils, etc. Transmission, in the same way by flies is a possibility.

Outbreaks of Sonne dysentery usually arise in a children's ward from the admission of a case in which the stools are not typical of the disease on inspection. Thus very mild cases and convalescent cases constitute the chief danger. D. Nabarro and A. G. Signy (1932) report that children who have recovered from an attack may continue to pass Sonne bacilli in the faeces "for months." This must, I think, be very rare, and it does not seem that the chronic carrier constitutes a problem of importance among children. The bacilli may disappear from the stools within as short a time as ten days from the onset of symptoms, and in my experience, in the absence of any relapse, tests have always proved negative by the end of three or four weeks. The incubation period is from one to eight days, usually two or three days.

Morbid Anatomy

Necropsies on cases of Sonne dysentery are so rare that I have not been able to obtain any first-hand information

Results

Serum of Patients Injected with Human Urine of Pregnancy Extracts.—The results of these assays (Table II) show that no appreciable amount of anti-gonadotropic substance is formed in response to the prolonged administration of either pregnyl or antuitrin S. The serum of Case II, which was tested most frequently, showed after nineteen weeks of injections a slight anti-gonadotropic activity, in that it inhibited, in an amount of 1.5 c.cm., the activity contained in about 0.5 mg. of the extract UP10. No further production was found in samples taken at a later date, in spite of the continued injections. This amount of anti-gonadotropic substance is very slight in comparison with that formed in other species receiving continued injection of this material (Rowlands and Parkes, 1937). Direct comparison is difficult, on account of the difference in the amounts given and the method of administration. The development of this small amount of anti-gonadotropic activity might be explained on the assumption that the pregnyl had been denatured to such an extent in its preparation as to become slightly antigenic to man.

These results confirm the work of Twombly (1936) and are in keeping with those of Thompson (1937) and Rowlands (1937a), who failed to produce "anti-hormone" activity in the blood of sheep that had been injected for prolonged periods with sheep pituitary extracts: they uphold the view of the true antibody nature of "anti-hormones."

Serum of Patients Treated with Pig Pituitary Extracts.—The serum of the patient (Case 3) treated with aminbin for sixteen weeks appeared to augment the gonadotropic activity of a saline extract of pig pituitary. When the test was repeated after twenty-one weeks of treatment the serum again appeared to enhance the activity of an extract made from acetone-desiccated pig pituitary (AP43D). A final sample of serum taken five weeks later failed either to augment or to inhibit the action of aminbin (AP44). The injection together with aminbin (AP51) of serum obtained before treatment (Cases 9 and 10) did not increase the effect of the extract on the rat ovary. Very doubtful augmentary effects were given by the serum of the patient (Case 4) treated with antuitrin gonadotropic.

The significance of an augmentary action, such as seems to be shown by these sera, is discussed elsewhere (Rowlands, 1937a).

Summary

No serious amount of anti-gonadotropic activity was demonstrable in the serum of patients receiving gonadotropic extracts of either human urine of pregnancy or pig pituitary for varying periods up to seven months. From this we conclude that in the treatment of undescended testes and other disabilities the administration of gonadotropic hormones may be continued for a considerable period without fear of inducing a phase of insensitivity and damage to the gonads by anti-gonadotropic substances.

We wish to thank Dr. J. Stanley White, of Messrs. Parke, Davis and Co. Ltd., for supplies of antuitrin S and antuitrin gonadotropic, and Dr. A. N. Macbeth, of Organon Laboratories, for supplies of pregnyl and aminbin.

THE WATER REQUIREMENTS OF
SURGICAL PATIENTS*

BY

D. L. C. BINGHAM, F.R.C.S.Ed.

Clinical Tutor, Surgical Out-patients Department, Royal
Infirmary, Edinburgh

This paper is a preliminary survey of the metabolism of the surgical patient during the immediate post-operative period, and is based upon results obtained while investigating the water balance of such subjects. It became evident very early in the investigation that water metabolism is only one of the many metabolic processes occurring in the surgical patient of which knowledge is far from complete. In this paper only water metabolism will be discussed; other aspects of metabolism will merely be noticed as each becomes relevant.

Water is essential for all the physiological processes of the animal organism, and the regulation of its intake and output is finely adjusted. This delicate regulation of intake and output is called water balance. In spite of its importance, only in the last ten years have accurate investigations been made into this subject, and although much is already known the water exchanges of the ill patient abound in unsolved problems. The researches of Maddock and Collier; Newburgh, Wiley, and Johnstone; and Laviets, Harrison, and Peters are all of the first importance, and should be consulted by students of the subject.

It is estimated that water forms from 65 per cent. to 70 per cent. of the body weight. This water is distributed in approximately the following proportions:

				Per cent. body weight
Extracellular fluids:	(1) Blood stream	9
	(2) Interstitial tissues	16
Intracellular fluid	45
Total	70

The functions of the extracellular fluids are threefold: to carry foodstuffs to the cells; to carry waste products away from the cells; and to regulate the stability of certain physico-chemical conditions in the body—pH, osmotic pressure, temperature, etc. For the perfect performance of these functions there is an optimum volume of the extracellular fluids, and departures from this optimum in either direction prejudice and may even threaten the actual life of the body cells. Alterations in the body fluids are largely made up of changes in the extracellular fluids, the intracellular fluids remaining comparatively constant until the approach of death.

The Study of Water Metabolism

Water metabolism may be studied by direct or by indirect methods. The direct method requires a knowledge of the following:

1. Water content of the fluids drunk.
2. Water content of ingested foods which may vary from 5 per cent. to 95 per cent.
3. Water formed by oxidation of this food.
4. Calorie output from its oxidation. (In this investigation it has been assumed that all the food ingested has been completely absorbed and metabolized.)
5. The approximate calorific requirements of the subject. (In the investigation the Douglas bag method was adopted, with due regard to its serious potential error when applying

* Report of work done while in receipt of a British Medical Association research scholarship.

neither of these things and is best avoided, nor should any other form of aperient be prescribed. Opium is the most useful drug in cases of this disease, and it may be taken with bismuth or a reliable brand of kaolin. Fluids should be given so far as the vomiting permits, and as soon as there is a desire for food a bland diet may be ordered. In debilitated patients special measures to combat the dehydration may be required. The use of anti-dysenteric serum is neither necessary nor of value in cases of Sonne dysentery.

THE ABSENCE OF ANTI-GONADOTROPIC SUBSTANCES IN THE BLOOD SERUM OF MAN INJECTED WITH GONADOTROPIC EXTRACTS

BY

A. W. SPENCE, M.A., M.D., F.R.C.P.

Assistant Physician, St. Bartholomew's Hospital

AND

I. W. ROWLANDS, Ph.D.

National Institute for Medical Research, Hampstead

Recent work has demonstrated that the prolonged administration of gonadotropic hormones to animals produces a state of insensitivity, so that the initial hypertrophy of the gonads disappears and may even be followed by atrophy (Collip, 1934). Moreover, the serum of an animal injected for about three months with a gonadotropic extract acquires the property of inhibiting the action of the gonadotropic extract when both are separately injected into a test animal, such as the immature rat; when the serum alone is injected into a normal adult animal it may cause atrophy of the reproductive organs (Rowlands, 1937). These phenomena are due to the production of anti-gonadotropic substances in the blood as a result of the continued administration of the gonadotropic extract.

These facts might be of clinical importance in the treatment of patients for a prolonged period with gonadotropic hormones. Should such anti-gonadotropic substances be formed in the human it would appear advisable to intersperse rest periods of several months, during which the patient receives no treatment, to enable him to re-acquire sensitivity and to prevent any possible damage to the gonads. On the other hand, should there be no indication of the production of such substances as a result of prolonged treatment these rest periods would be unnecessary. In the elucidation of this problem samples of blood from nine patients with undescended testes who were receiving treatment with gonadotropic hormones were tested for anti-gonadotropic activity.

Methods

The patients were injected intramuscularly twice a week with extracts of human urine of pregnancy (pregnyl or antuitrin S) or with extracts of pig anterior pituitary (ambinon or antuitrin gonadotropic). Details of their treatment are given in Table I.

TABLE I.—The Treatment of the Patients with Gonadotropic Preparations

Case No.	Age (Years)	Preparation	Dose (Rat Units, R.U.) twice weekly
1	19	Pregnyl	1,000
2	12	Pregnyl	500 for first 9 weeks, then 1,000
7	14	Pregnyl	1,000
8	20	Pregnyl	1,000
9	12	Pregnyl	500
10	14	Pregnyl	500
5	13	Antuitrin S	200
3	14	Ambinon	50
4	10	Antuitrin gonadotropic	30 for first 14 weeks, then 50 for 9 weeks

Where possible a sample of blood was obtained before treatment and thereafter at intervals of one to two months for as long as was practicable in each case (Table II). About 20 c.cm. of blood was obtained from the basilic vein, and kept in a sterile flask at 0° C. until the following morning, when the serum was separated. The activity of the serum was measured by its capacity to neutralize, in the immature rat, the power of a gonadotropic extract similar to that injected into the patient. Each sample of serum and gonadotropic extract was injected into a group of five immature female rats (40–50 grammes) once daily for five days; the two injections were given on opposite sides of each animal. The rats were killed twenty-four hours after the last injection, and the ovaries dissected, fixed in Bouin's fluid, and weighed the following day from 70 per cent. alcohol.

A gonadotropic extract from human urine of pregnancy (UP10) was used in testing, of which a total dose of 1 mg., divided over five days, produces ovaries weighing 35 mg. in the immature rat. The weight of the normal ovaries of rats of this body weight is 10–12 mg. The activity of the other extracts used is given in Table II.

five-minute readings to the whole twenty-four-hour period. Also it was sometimes impossible to obtain results because the patients would not tolerate the procedure.)

6. If, as is the rule in the ill patient, the calorie requirements are not met by the food intake, then the water formed from the oxidation of body tissues must be estimated. This requires a knowledge as to which of the body constituents are providing the necessary energy, in itself a laborious investigation.

7. The solid intake.

8. The solid output in the urine, faeces, sputum, vomitus, and other discharges. (The solids lost in the sweat have been ignored.)

9. The fluid output in the urine, faeces, and insensible perspiration from the skin and lungs. (Insensible perspiration and insensible loss of weight are not the same. Insensible perspiration implies lost water only. Insensible loss of weight is equal to lost water plus carbon dioxide minus gained oxygen, and varies with the respiratory quotient. In this paper insensible perspiration has been taken to be equal to insensible loss of weight.)

10. The body weight under standard conditions of nudity, after emptying the bladder, and at fixed times during the day.

The direct method of estimating water balance may be expressed in the following two equations:

$$1. \text{ Change in weight} = \left\{ \begin{array}{l} \text{solids in} \\ \text{fluids in} \end{array} \right\} - \left\{ \begin{array}{l} \text{solids lost (urine, faeces, vomitus, etc.;} \\ \text{body solids metabolized)} \\ \text{fluids lost (urine, faeces, vomitus, etc.,} \\ \text{insensible perspiration)} \end{array} \right\}$$

For insensible perspiration this equation may be expressed:

$$\text{Insensible loss} = \left\{ \begin{array}{l} \text{solids in} \\ \text{fluids in} \end{array} \right\} - \left\{ \begin{array}{l} \text{solids lost} \\ \text{visible fluid lost (urine,} \\ \text{faeces, vomitus)} \end{array} \right\} - \text{change in weight}$$

$$2. \text{ Water balance} = \text{fluids available} = \left\{ \begin{array}{l} (1) \text{ in fluid drunk} \\ (2) \text{ in food} \\ (3) \text{ formed by meta-} \\ \text{bolism of either} \\ \text{food or body tissues} \end{array} \right\} - \left\{ \begin{array}{l} \text{visible fluid lost} \\ \text{insensible fluid} \\ \text{lost} \end{array} \right\}$$

Indirect methods are perhaps more complex; they require that a number of no doubt allowable assumptions be made, and are essentially a study of the metabolism of certain electrolytes from which the water exchanges may be calculated (Laviates, 1935, 1935a). In this investigation the first direct method has been followed.

At this stage it is necessary to study more closely the water gained and lost through the various channels.

WATER GAINED

(a) The volume of the fluids drunk varies considerably with the individual. In health from 800 to 2,000 c.cm. may be taken daily. After operations the patient may be able to tolerate only 200 c.cm. or less during the first twenty-four to forty-eight hours without nausea.

(b) The metabolic mixture provides in water content and from water of oxidation 1,000 c.cm. to 2,000 c.cm. daily.

During starvation about 500 c.cm. of water becomes available from the tissue katabolism made necessary by the energy requirements.

WATER LOSS

1. *In the Urine.*—The water lost in the urine is the amount which remains after insensible perspiration has withdrawn its quota from the body water available for excretory purposes. It follows, therefore, that if the body is seriously dehydrated the patient is often anuric, and the dehydration should be overcome before other measures are taken to promote the secretion of urine. It is here pertinent to point out that the kidneys are required to excrete daily in health about 35 grammes of waste materials. Unless sufficient water is available for this

purpose retention of these waste products occurs. Where renal damage exists more water is required to excrete the same quantity of waste material. The following table is interesting in this connexion:

	Maximum Concentrating Ability	Minimum Water Required to Excrete 35 grammes of Waste Products
Normal kidneys	c.cm. 1,032—1,029	c.cm. 473
Diseased kidney .. .	1,028—1,025	595
	1,024—1,020	605
	1,019—1,015	850
	1,014—1,010	1,439

It follows from these observations that, knowing the degree of renal damage in any given patient, we must never allow the urinary volume to fall below the minimal water volume which is necessary to excrete the patient's urinary waste products. Indeed, as the waste products to be excreted in the post-operative period may greatly exceed 35 grammes, the surgeon's aim must be to ensure that the patient has at least double the above minimal volume of water available for urinary excretion.

2. *In the Faeces.*—On an average 150 c.cm. of water are lost daily in the faeces.

3. *From the Skin and the Breath.*—Normally the volume of water vaporized from the skin and in the breath varies from 800 to 1,500 c.cm. daily; but in abnormal conditions of high external temperature or humidity, or in diseased states such as thyrotoxicosis, fever, etc., these figures may be greatly exceeded. Indeed, as much as 3,500 to 4,000 c.cm. may be lost daily in the breath and from the skin. This water of vaporization is responsible for the thermal control of the body, and dissipates about 24 per cent. of the body heat. Each c.cm. of water requires 0.58 large calorie for its vaporization; therefore, if the insensible water loss be 100 c.cm. it will require 58 calories to effect its vaporization. Owing to its all-important function of temperature regulation the insensible perspiration exercises preferential rights over all water available for excretion. It is not until over 6 per cent. of the body weight has been lost in fluids that any decrease in water vaporized occurs. At this stage the patient is grossly dehydrated, is fevered, is anuric, has sunken eyes, a dry skin, and a dirty dry-leather-like tongue. If water be now given it is retained by the body until the deficit is made good before any becomes available for the restoration of the other excretory processes, such as renal excretion, the faeces, etc.

4. *Loss by Other Channels.*—The loss of water by other channels such as by vomiting and from fistulae, etc., may be great. It is said that severe and rapid dehydration does not occur except by these methods, especially by vomiting. Where there is excessive vomiting, etc., the volume lost must be estimated and added to the fluid intake if water balance is to be maintained.

Results of the Investigation

In the present investigation ten unselected cases were taken, all of which were treated by the usual routine methods of the surgical wards of the Royal Infirmary, Edinburgh. The accompanying table abstracts the pertinent results.

From an inspection of the table it will be seen that:

(a) Following operation each patient became increasingly dehydrated during the period of study, the smallest

grey slough, which was apparently typical. Her doctor told me that these areas took about eight to twelve weeks to heal with the paraffin and flavine dressings which had been advised. I asked her when she expected them to have healed, and the patient replied, "By about Christmas. Not much before, I suppose." Insulin dressings, double strength, were started, and as the patient lived in the country these could be applied only once a day. In this case I sprayed the insulin on with a hypodermic syringe, then covered the wound with gauze and again sprayed with insulin. The whole was then covered with mackintosh, wool, and a bandage. One week later, on September 24, the area had healed over.

The effect in every case treated has been so remarkable—a complete cure being the end-result in all except Case 3, and this has been relieved—that the treatment seems at least worthy of further investigation. In only one case, No. 1, was the patient in hospital, where adequately supervised dressings could be applied. No. 2 attended for twenty-four-hourly dressings each morning. The remainder were seen and treated at home, with only medically supervised dressing once a day.

The cost of this treatment is obviously a factor, since a considerable amount of insulin is used in the dressings. Up to date only the ordinary single- and double-strength insulin, as put up for diabetics, has been employed; but I am approaching a firm of manufacturing chemists with a view to obtaining it in ointment form.*

The reasons underlying the effect of insulin on such conditions seem a little obscure. The only explanation I can offer which seems reasonable is that by stimulating the local metabolism of sugar the cell proliferation and local health are increased. It is certain that excess of sugar is inimical to healthy cellular metabolism, as is seen by the lowered resistance to infections in persons suffering from diabetes mellitus. There was no reducing substance in the urine of the patients treated by local applications.

My thanks are due to Mr. E. P. Brockman, F.R.C.S., for permission to publish the first case detailed and Dr. W. Dalgliesh for Nos. 3 and 4.

Treatment of Mooren's Ulcer with Liver Extract

I had the opportunity of observing and treating the following two cases at the Bristol Eye Hospital while house-surgeon there in 1935.

CASE I

A woman aged 60 first attended on March 21, 1934, with Mooren's ulcer of the right cornea, which steadily developed in spite of treatment until the whole cornea was involved. Median canthoplasty was performed on October 24, 1934. At about this time a similar ulcer made its appearance in the left eye. This also developed slowly until by May, 1935, it was half-way across the pupil. I obtained permission to try the patient on injections of liver extract in the belief that the liver would improve the nutrition of the cornea and thus help the ulcer to heal. I prescribed one ampoule of "campolon" (Bayer) once daily for a week, and then one ampoule every other day for three weeks. The Metri cautery (80°–85° F.) was applied to the margins of the ulcer for one minute every second day. A saline wash twice daily was the only other treatment. One month later the patient was discharged, the ulcer being quite healed. She attended every fortnight for an injection of one ampoule of "campolon." The adhesions

between the right eyelids were divided two months after her discharge. The cornea was very thin and scarred, but did not stain in any part of it. The ulcers have remained healed ever since, and both eyes were reported "quiet" on June 26, 1937.

CASE II

This patient, a man aged 57, was first seen on January 2, 1935, for Mooren's ulcer of the right eye. This steadily extended until he was put on similar liver treatment on June 6. He was discharged five weeks later with the ulcer healed. He was instructed to get fortnightly injections of one ampoule of "campolon" from his own doctor, but neglected to do so. The ulcer broke down again, and he was readmitted on August 30. After a week's treatment on liver injections the ulcer had healed and the patient was discharged. He was last seen on May 20, 1936, and up to that time the eye had remained quiet.

I am much indebted to Mr. A. E. Iles, senior honorary surgeon to the Bristol Eye Hospital, for letting me have a copy of the notes on these cases and for his permission to submit them for publication.

Cork.

CHARLES J. CANTILLON, D.O.M.S.,
D.O.(Oxon).

A Method of Treating Fractures of the Lower Leg

It may be worth while to give a short account of this method of dealing with fractures of the lower leg because of its great simplicity and because of certain advantages it has over methods at present in use. The technique can be employed for almost any fracture of the lower leg which requires reduction and application of plaster. The only apparatus needed is a ring fixed on the theatre floor; a heavy weight with a ring attached serves the same purpose.

TECHNIQUE

The patient is anaesthetized and a Kirschner wire is put through the calcaneus two fingerbreadths below and one behind the lateral malleolus. He is then arranged on the operating table with both knees flexed over the end so that the ring on the floor is in line with the injured limb, but six inches in front of the vertical. The Kirschner horseshoe is fixed with extension cord to the ring, a traction indicator intervening. The surgeon now sits opposite the fractured leg and directs an assistant, who pumps up the table slowly. In this way strong traction can be produced which will bring the fragments of the most difficult fracture into alignment. The surgeon, by palpation and comparison with the other leg, which is hanging over the end of the table in the same position, finds that very little manipulation is required to obtain an almost perfect reduction. The leg is in the optimum position for the easy application of a well-fitting plaster. Slight pressure on the inner side of the setting plaster allows for the normal bowing of the tibia.

If the fracture is in the upper third of the tibia the plaster may be extended to the groin when the lower part has set, or a second Kirschner wire may be put through the tubercle of the tibia and incorporated in the plaster, thus leaving a freely movable knee and fixing the upper fragment.

The advantages put forward for this method of treating fractures are: (1) that it requires no elaborate apparatus and is therefore particularly useful in smaller hospitals which do not possess such equipment; (2) that an almost perfect reduction can be obtained, since there is no difficulty caused by the fractured leg sagging in the middle, as is always the case when traction is applied in the horizontal position, this being especially troublesome if the fracture is comminuted; (3) that the leg is in the ideal position for easy and efficient plastering, so that this part of the operation and the reduction can be performed in a relatively short time.

A large number of fractures of the lower leg have been treated this way with very satisfactory immediate and end results.

DOUGLAS LANG STEVENSON, F.R.C.S.Ed.

* This has since been done, and Messrs. Allen and Hanbury prepare such an ointment. Cases treated with this have been equally successful.

negative water balance at the end of the second day after operation being 679 c.cm. and the largest 3,565 c.cm. at the end of the third day. No patient maintained normal water balance. Each case varied considerably, but even with an uneventful convalescence it was not usually until the fifth day that normal water balance was re-established.

(b) The insensible water loss was very considerable, especially in the first twenty-four hours, possibly from the effects of the anaesthetic. This insensible water loss was always very great when the patient perspired profusely, and varied from 1,000 to 2,400 c.cm. (1.65 to 4 pints).

(c) Coincidentally with dehydration there was a noticeable decrease in urinary secretion (even to its abolition); a rise in blood urea nitrogen, indicating waste-product retention; and a decrease in the CO_2 combining power of the blood.

(d) Not shown on this table, but coincidentally with dehydration and the limitation of the patient's caloric intake, there was very marked katabolism of body protein, to facilitate the katabolism of body fat for energy requirements, as the carbohydrate reserves are rapidly exhausted. Amounts up to 250 grammes of body protein burnt per day were observed in the first twenty-four to forty-eight hours after operation. With the restoration of water balance it was remarkable that this excessive destruction of body protein ceased.

(e) Clinically the state of the tongue and oliguria and the subjective sensation of thirst indicate dehydration.

Conclusions

1. Under the existing post-operative regime dehydration occurs, and may be severe.

2. Although each case must be separately considered the minimal fluid intake in the days following operation should be from 3,000 to 4,000 c.cm. a day (approximately 5 to 7 pints), if necessary by the intravenous route. (In a further communication the most suitable fluid will be discussed.)

3. If excessive loss from vomiting, etc., occurs the extra volume of fluids so lost must be added to the amount which the patient in any case requires.

4. Oliguria, thirst, and a filthy dry tongue are a real reproach to the surgeon.

A most pleasant duty is the acknowledgment of my debt to others. To Sir John Fraser for the privilege of working in his wards, and to his staff for their patient help; to the technical staff of the Biochemical Laboratories; and to Professor Melville Dunlop for his unfailing encouragement, my grateful thanks are due.

Clinical Memoranda

Insulin in the Local Treatment of Persistent Septic Cutaneous Conditions

The use of insulin for the treatment of diabetes mellitus is now world-wide, but the extraordinary effect of this substance in securing the cure of persistent cutaneous septic conditions seems up to the present time not to have been realized.

The work of da Costa and others in connexion with the insulin treatment of epitheliomatous ulcers first drew attention to the possibility of using it in cases of chronic cutaneous sepsis that had proved resistant to all other remedies. The following four cases are typical and represent the varying types of septic conditions treated, the clinical features and treatment being given in detail.

ILLUSTRATIVE CASES

Case 1.—A boy aged 14 was involved in a motor accident in October, 1936, and on November 11 following underwent an exploratory operation in the region of the left elbow. Subsequently the wound broke down. Ultra-violet rays and sunlight treatment as well as the usual dressings were tried, with no success. The patient was admitted to the Westminster Hospital for excision of the skin in the region of the unhealed area. This was done and the wound again sutured, but it broke down immediately. The patient was subsequently readmitted for twice-daily dressings. First cod-liver oil was tried and then antipeol, with no success at all. Insulin dressings were started on March 20, 1937, and applied twice daily by the nursing staff. Rapid healing took place, and the patient was discharged on April 8, with the wound closed for the first time since November, 1936. He has been seen since, and has had no further recurrence of the breaking down of the wound.

Case 2.—This patient was seen in the casualty department, which she had been attending for over a month with a septic finger. In spite of all forms of treatment it was getting worse, to the despair of the casualty officers and the sister in charge. I saw it, and suggested that daily insulin dressings should be tried. These were started at once, and within ten days the finger was quite well and the patient had returned to work.

Case 3.—A man aged 57 was first seen by me in March, 1936, with an amputation of the right leg following arteriosclerosis. He had an infected bunion on the left leg opposite the head of the first metatarsal which had ulcerated and was giving him considerable pain. Ordinary dressings were continued until August, 1937—that is, for sixteen months. The patient was in some pain all this time, particularly when he attempted to walk. He came into my hands again on August 27, 1937, when I suggested insulin treatment locally. This was started on August 29, the man dressing the foot himself three times daily with single-strength insulin on gauze. When seen five days later the patient said he was much more comfortable, and one week after this the pain had gone. The ulcer was shallower, and the area of inflammation surrounding it had entirely disappeared for the first time. It is scarcely to be expected that the ulcer will heal, owing to the continual movement and lack of any pulsation in the peroneal and tibial arteries.

Case 4.—A married woman aged 27 was first seen by me on September 14, 1937. Her history was a peculiar one. After working for some time in a blanket factory she found that whenever she knocked herself the bruised place became septic. This condition was a surface inflammation which took a long time to heal, and when it did it left a white scar. Her right arm was covered with these scars. When examined at the Radcliffe Infirmary a diagnosis of low-grade streptococcal infection was made. At the time I saw her she had one of these septic areas on her left arm, irregular in outline and about two inches by one inch in extent, raw, with a yellow

and well illustrated. Passages here and there both instruct and amuse, particularly when reference is made to individual obstetricians. On page 587 we read: "When an obstetrician informs me that he never employs vaginal hysterotomy I turn away in sadness. To discuss a subject with one so prejudiced is only a waste of time." By undertaking the labour of a fourth edition of his work Munro Kerr has rendered a service to the science and art of obstetrics.

POST-MORTEM TECHNIQUE

The Postmortem Examination. By Sidney Farber, M.D. (Pp. 201; frontispiece and 32 figures. 16s.) Springfield and Baltimore: Charles C. Thomas; London: Baillière, Tindall and Cox. 1937.

This book, devoted entirely to post-mortem technique, may be recommended to all embryo pathologists as an excellent guide to the subject. It will also be of use to the general practitioner who may suddenly be called upon to perform a necropsy. The opening chapter is devoted to a short historical survey, and this is followed by chapters on general considerations and on the equipment of the post-mortem room. The rest of the book consists of a detailed description of the methods to be employed in the examination of each system of the body, and each chapter ends with a short list of selected references. An appendix contains tables giving the average weights of organs, and also an interesting translation of one of Virchow's original elaborate post-mortem reports.

Some of the techniques described, such as the method for the removal of the thoracic viscera, differ from those usually employed in this country. They may, however, be used with safety, as they are, for the most part, similar to the methods originally recommended by Virchow, which it would be found hard to better.

NEUROLOGICAL STUDIES

Etudes Neurologiques: Les Myoclonies Vêlo-Pharyngo-Laryngo-Oculo-Diaphragmatiques, La Maladie de Friedreich, Pathologie du Névrose. By Georges Guillain and Pierre Mollaret. Septième série. (Pp. 302; 78 figures. 60 fr.) Paris: Masson et Cie. 1936.

In the seventh series of his neurological studies Professor Guillain, with the assistance of Dr. Mollaret, concentrates especially on two subjects—the syndrome of rhythmic myoclonus of the palate, larynx, and ocular and diaphragmatic muscles, and the bulbar symptoms of Friedreich's ataxia. In regard to the former, several new clinical and pathological observations are recorded, and from these and the earlier papers of the French school we can form a fairly complete conception of the syndrome.

While our present knowledge of anatomy and physiology does not afford an adequate explanation for any of the phenomena of involuntary movement, whether rhythmic or choreiform, any new material bearing on this subject is of importance. The fact that each syndrome of this character is most often produced by a lesion in one situation is discounted by observations of similar symptoms appearing when the lesion is in some other centre which at first sight seems to have no close connexion with the tract or nucleus most commonly involved. In the earlier papers on the syndrome under discussion the lesions were almost always found to involve the central tegmental tract in the pons. But in later cases in which the syndrome was present in its most complete form lesions of this tract were absent, and either the inferior olive, the dentate nucleus, or the superior cerebellar peduncle was involved. It thus appears that the

syndrome of rhythmic myoclonus may be seen after any lesion of the system represented by the red nucleus, the inferior olive, the dentate nucleus, and their connexions with each other. More than this is not known, nor is it clear why all lesions of this system are not followed by the syndrome.

The studies on Friedreich's ataxia pay special attention to the lesions in the medulla oblongata and to the symptoms resulting from these. In spite of many references to cardiac symptoms, such as tachycardia, in the literature from the time of Friedreich onwards, the dependence of these symptoms on medullary lesions has not been previously emphasized. Guillain and Mollaret point out the frequency of abnormalities in the electrocardiogram in Friedreich's ataxia, and demonstrate lesions in the nuclei of the vagus which may cause them. These observations may explain the paradox that while victims of Friedreich's ataxia do not die of their disease, most of them die young.

Several minor papers on diseases of the brain and spinal cord are also included in this series.

POISONOUS ORGANIC SOLVENTS

Medical Research Council Industrial Health Research Board. Report No. 80. *Toxicity of Industrial Organic Solvents.* Summaries of published work compiled by Ethel Browning under the direction of the Committee on the Toxicity of Industrial Solvents. (Pp. 396. 7s. 6d. net, postage extra.) London: H.M. Stationery Office. 1937.

This is a compilation of existing information prepared by Dr. Ethel Browning. The report deals with no fewer than 100 different compounds, all of which are at present in use in industry. A striking feature of the book is the wide variety of literature from which the information has been collected. A large proportion of the references is to journals devoted to public health and hygiene, but in addition there are numerous references to chemical, biochemical, pharmacological, pathological, and clinical journals. There also are references to specialist medical journals in such subjects as dermatology, haematology, and psychology, and to agricultural and trade journals. The author is to be congratulated on the industry she has shown in collecting information from such a wide variety of sources. The volume therefore represents a useful advance in knowledge, since the mere dispersal of the data collected has rendered them hitherto inaccessible to the ordinary reader.

The committee in an introduction points out that the information available is on the whole very incomplete. It remarks: "For example, the effect of the subcutaneous injection of a large dose of substance may be entirely different from, and have little bearing upon, the effects which may be produced by prolonged inhalation of small quantities." Moreover, "owing to expense and the difficulties of housing large animals, preliminary investigations are nearly always made on small animals. Unfortunately no general rules can be laid down which relate the sensitivity to poisons of small rodents and of man." It is to be hoped that the imperfect nature of the evidence revealed by this survey will stimulate research in this important field of industrial hygiene, which is developing so rapidly.

The character of the volume, which is that of a condensed summary of a very large literature, renders it unsuitable for detailed review. The importance of the subject is obvious, and the value of the report can most easily be realized by calculating in the case of any one of the lists of references how long it would take a research

Reviews

RADIOTHERAPY FOR CANCER

Sechzehn Jahre Strahlentherapie der Krebse. Zürcher Erfahrungen 1919-1935. By Hans R. Schinz and Adolf Zuppinger. (Pp. 340; 95 figures, 215 tables. Rm. 32; G.R.M. 14.) Leipzig: Georg Thieme, 1937.

In this very interesting work on sixteen years' experience of radiotherapy in cancer Drs. Schinz and Zuppinger give an account of their work at Zürich from 1919 to 1935, during which period Dr. Schinz has been director of the Roentgen Institute. The canton of Zürich is the main industrial and manufacturing centre of Switzerland, and its capital town of the same name is the most populous in the country. It is therefore of interest to learn that the mortality from cancer in this industrial centre is very similar to that in the rest of the Swiss Confederation, where conditions of occupation are generally very different. Approximately one-seventh of the total deaths recorded in the canton and town of Zürich are caused by cancer, and the figures have increased in recent years. The authors do not regard this increase as being due to multiplication of carcinogenic factors, but merely as a consequence of the increased longevity of the general population, so that more individuals reach the age of maximum liability to cancer. This is, of course, a view which is held by many other eminent authorities both in Europe and America. Although the general cancer mortality has increased, there has for some unexplained reason been a notable decline in the proportion of deaths from cancer of the stomach and uterus. The site incidence of the disease is different in the two sexes. In men, the regions most affected are the stomach, oesophagus, rectum, intestine, pharynx, and lungs; in women, the stomach, breast, uterus, and ovary, which are closely followed by the colon and gall-bladder region. The histological types of growth also show differences in the two sexes. In men, squamous-cell carcinoma is by far the preponderant type; while in women it is much less common, except in cancer of the cervix uteri.

By far the largest part of the book deals with the results obtained in the treatment of cancer in different sites, and a simple and useful formula for indicating briefly the extent both of primary and metastatic growths is proposed. This should be of considerable service in record-keeping, for it shows at a glance the degree both of local extension and of dissemination reached in each particular case when recorded. The subject-matter generally is clearly set out and in many cases conveniently epitomized in tabular form.

There are some points in the history of the Zürich Roentgen Institute which are of interest. It began as a small diagnostic unit under the control of the surgical clinic, and before 1918 it was enlarged by the addition of a radiotherapeutic department, since when its work has been greatly developed and extended, but Dr. Schinz and his colleague observe that this has been terribly uphill work. In spite of the fact that in 1926 the director received the title of professor of medical radiology, his department still remains under the control of the department of surgery. A similar condition of affairs unfortunately still exists in some places in this country, in which a radiotherapeutic department has been developed from small beginnings in a general hospital. If we are to secure and retain the services of the best men and women as radiotherapists they must be accorded the

position and security due to their professional attainments and experience. The authors of this book have done a real public service in stating so clearly the conditions under which they have been compelled to work, and we hope that the Zürich Institute of Radiotherapy will soon obtain the independent position to which its excellent work and the high scientific attainments of the director and staff give an unquestionable title.

OPERATIVE OBSTETRICS

Operative Obstetrics: A Guide to the Difficulties and Complications of Obstetric Practice. By J. M. Munro Kerr, LL.D., M.D., F.C.O.G., with the assistance of Donald McIntyre, M.D., F.C.O.G., etc., and D. Fyle Anderson, M.D. Fourth edition. (Pp. 848; 338 illustrations. 45s.) London: Baillière, Tindall and Cox, 1937.

After an interval of twenty-one years Professor Munro Kerr has brought out the fourth edition of his well-known book, with the assistance of two other members of the Glasgow school—namely, Drs. McIntyre and Fyle Anderson. In spite of the change of title from "Operative Midwifery" to "Operative Obstetrics" it retains the distinctive individuality that made its predecessors so acceptable. The work rests on a sure foundation—the extensive experience of the author both as teacher and as clinician—and his personality pervades the whole 800 pages.

So much time has elapsed that it is not surprising to find a great deal of the book rewritten; and while Munro Kerr states clearly his own views regarding treatment and results, he enhances the value and interest of each chapter by references to recent publications by authorities in both Europe and America. After introductory pages on the management of labour and the prevention of infection, dystocia due to the various causes is taken up chapter by chapter. Malpresentations, tumours, inertia, contracted pelvis, the haemorrhages, abdominal and vaginal operations—all these are discussed clearly in an attractive manner. As will be expected from the frequency of its incidence, the occipito-posterior case is early considered and fully described, and the original point of view is maintained that such cases may be primary or secondary. In discussing the engagement of the head in vertex cases the author emphasizes the frequency with which the head engages in the transverse diameter of the brim in normal cases. The emphasis on this point is a source of satisfaction to the reviewer, who has for some years held the same view. Contracted pelvis is dealt with in the light of recent research, reference being made to the work of Caldwell, Moloy, and others. The methods employed for induction of labour are fully described and the risks of various methods assessed; and while the author appreciates the value of rupturing the membranes when indications are present he issues a timely warning to his readers against the present tendency in some centres to adopt such intervention almost as a routine procedure.

It is impossible to refer to each chapter separately, but mention should be made of that on Caesarean section—one of the best in the book. As one of the earliest and strongest advocates of the lower segment operation Munro Kerr stresses its advantages over the classical procedure in the hands of the experienced operator. The frequency with which the placenta is found on the anterior wall of the uterus at Caesarean operations; the difficulty of obtaining a sound scar in such cases; the likelihood of subsequent rupture if the placenta develops on this scar—these points are all brought out in the argument against the classical incision as a routine.

In covering the range of difficult midwifery the author has produced a book worthy of study, eminently readable

seventeen different headings. Turning to a group showing a salient feature of the case in hand the reader finds a subclassification and may at once find the solution; or he may be referred to another group, finding again a subclassification in which his case lies. The reviewer can only say he has put it to the test and found it to work perfectly. The possible and obvious limitation is that some disease has been omitted—but he cannot point to it. The author mentions many points of clinical interest—for example, high calcification of the teeth in children in hyperparathyroidism, the existence of germs in apical granulomata (Figs. 21 and 22), contraction of the maxillae due to adenoids, and hypoplasia of the roots of the teeth in osteogenesis imperfecta. The book is a valuable contribution to dental literature.

Japanische Literatur zur Tuberkuloseforschung, No. 5 (1936), published by the Society for Tuberculosis Research of the Anatomical Institute of the University of Kyoto, contains abstracts, numbered 484 to 620, mostly in German and the remainder in English, of published Japanese papers on research work in tuberculosis, received as reprints in the library of the Society since 1930. The publishers of this pamphlet are prepared to send to anyone specially interested in any particular article a detailed report of it, free of cost, or to refer a request for the actual paper to the appropriate author.

In his work on *Early Medieval Medicine* (Baltimore: Johns Hopkins Press, 1937, 12s. 6d.), which forms the Hideyo Noguchi Lectures for 1936, Professor LOREN C. MACKINNEY, who holds the chair of mediaeval history in the University of North Carolina but is not a medical man, has given an interesting description of medicine in that portion of the Middle Ages extending from the sixth to the eleventh century. "Two distinct types of medicine were then prevalent—namely, the supernatural, which included reliance on Christian saints and their relics and Christian-pagan charms and magical incantations; and human medicine, which is considered under the headings of pharmacy, diet, and surgery in the form of blood-letting and cauterization. In the first lecture Professor MacKinnery discusses the changing modern conception of the Middle Ages, and surveys certain general aspects of the medical practice prevalent in Western Europe during this era. In the second chapter, which is devoted to medicine in Merovingian and Carolingian France, the author shows that there was a steady advance in medical practice, while in the third lecture medical progress at Chartres in the tenth and eleventh centuries is discussed. Nearly eighty pages of instructive notes, followed by copies of mediaeval manuscripts, are appended.

Quelques Vérités Premières (Ou Soi-disant Telles) en Chirurgie Abdominale (Paris: Masson et Cie, 24 fr.) is a series of aphorisms relating to the practice of abdominal surgery, written by Dr. H. MONDOR, professor of surgical pathology in the Paris Faculty of Medicine and surgeon to the Bichat Hospital. It may be read with profit by students and general practitioners as well as surgeons. This volume forms one of a series of "first truths" relating to the different branches of medicine, some of which have already appeared, while others are still in the course of preparation. Following an introduction by MM. Ombredanne and Fiessinger the collection is divided into three chapters, the first dealing with the abdominal wall, stomach, duodenum, and pancreas, the second the intestines and peritoneum, and the third with gynaecology. As an example of the pithy nature of many of the sayings we may quote from this last section (p. 87): "Les hémorragies du fibrome sont des ménorrhagies. Les saignements du cancer sont des métrorrhagies." These aphorisms are well set out in large clear type on dull-surfaced paper, and make easy and stimulating reading. The idea appeals to us, and if the other volumes are as sound and attractive as this one on abdominal surgery the series should meet with well-deserved success.

Preparations and Appliances

INSTRUMENT FOR DETECTION OF OEDEMA

Professor W. C. W. NIXON, M.D., F.R.C.S., writes from the Obstetric and Gynaecological Unit of the University of Hong Kong:

For the detection of oedema pitting by means of finger pressure is a somewhat inaccurate method. I have noticed that by pressing with the bell of a stethoscope a well-marked "ring" impression is made upon an oedematous region, especially if it is one where there is no underlying bone—for instance, the abdominal wall. This instrument which has been devised incorporates not only the stethoscope bell but also a spring by which a known pressure for a known length of time can be exerted. The minimum pressure and the length of time found most suitable has been 2 lb. and five seconds respectively. The "ring" impression so made and the time it takes to disappear decide one as to whether the oedema can be classified as mild, moderate, or pronounced.

This method of testing for oedema has the advantage that it enables one to detect mild grades of oedema, particularly of the abdominal wall, which otherwise would pass unnoticed.

The makers of the instrument are Down Bros. Ltd., 21 and 23, St. Thomas's Street, London, S.E.1.

PREPARATIONS OF CALCIUM SALTS

"Calcipot" is a name for preparations of calcium salts made in Germany by Tropenwerke Dinklage and Co. and marketed by Harker, Stagg and Morgan Ltd. (Emmott Street, London, E.1). Tablets of calcipot D (1 gramme) contain 0.28 gramme of calcium citrate and 0.02 gramme of calcium glycerophosphate, together with vitamin B₁ (5 international units), vitamin B₂ (1.5 biological units), and vitamin D (0.9 clinical unit). It is recommended for calcium deficiency, particularly when this is associated with vitamin deficiency. Ampoules of calcipot (5 c.c.m.) contain 10 per cent. of calcium gluconate solution, and are supplied for intramuscular or intravenous injection. Injections of calcium gluconate have proved a valuable method for relieving such conditions as tetany when these are due to a sudden fall in blood calcium.

"FERRIPAN"

"Ferripan" (prepared by Tropenwerke Dinklage and Co. and marketed by Harker, Stagg and Morgan Ltd.) is a powder which contains fat-free purified liver, iron albumin, and copper albumin. It is recommended for treatment of deficiency or nutritional anaemias. The manufacturers publish clinical charts which show the superiority of ferripan over saccharated iron oxide in the treatment of nutritional anaemias of children.

EPHETONIN COMPOUND

Ephetonin compositum liquidum (E. Merck, Darmstadt) is a solution which contains 2 per cent. each of ephetonin and pyrazinecarboxylic acid-isopropylidene hydrazide. Ephetonin is phenylmethylaminopropanol, and may be described as synthetic ephedrine. It is stated to augment the force of cardiac contraction and to dilate the coronary vessels. The other constituent is stated to have a similar sympatho-mimetic action on the heart, and also to act as a central nervous system stimulant. The combination is recommended for the treatment of cardiovascular insufficiency. It is put up in drop bottles of 10 c.c.m. and 20 c.c.m. The distributors for this country are Savory and Moore Ltd., 61, Welbeck Street, W.1.

worker to find these references without the help of this volume. Although the evidence brought together is admittedly incomplete, yet this is obviously a case where any information is better than none, and the volume should prove of great value to all who are interested in industrial hygiene.

THE NATURE OF CRIME

The Criminals We Deserve. A Survey of Some Aspects of Crime in the Modern World. By Henry T. F. Rhodes. (Pp. 257; illustrated. 7s. 6d. net.) London: Methuen. 1937.

Crime is, broadly speaking, an act which breaks the rules of society, but emphasis is usually laid by criminologists on the crime or the criminal, and not on the social code which he infringes. Mr. Rhodes's theme is that society may be wrong too. To say that the responsibility for crime should rest equally on the criminal and on society is not a popular attitude, but more and more thinkers are becoming convinced that it is the only starting-point for a really effective attempt to abolish crime. Mr. Rhodes has an international training, another unpopular thing in this country but one which is likely to teach him more about crime in general than a purely domestic outlook. The commission of a crime, he says, is a blind and unconscious protest against the social conditions which help to determine it. Eventually, he prophesies, we shall become convinced that the only effective way to punish crime is to prevent it. Decent housing conditions would immensely reduce sexual and violent crimes; abundance of remunerative work for those who wanted it would reduce crimes of need. He doubts, however, whether any of these things can be done within a social system which produces for profit and not for use. He has no illusions about the possibility of eliminating crime by a change in the social system, but he thinks that the first step might be taken by constructing a system in which crime could be properly defined. He is much impressed by the Soviet prison system, which places the prisoner in a workshop where he can earn wages and have reasonable recreation and the utmost practicable freedom. In a place of this kind, where the contribution of society is reduced to a minimum, the criminologist will, says Mr. Rhodes, have some opportunity of discovering something about the anti-social man. He is extremely interesting; he writes well and fills his book with practical illustrations and facts. He deals with crime of all kinds, and tells many stories of single crimes to illustrate his opinion that crime, by peaceful penetration, is making itself an organic part of a system which is in decay.

Notes on Books

The ninetieth issue of *Who's Who*, for the year 1938, was published before Christmas, and maintains the standard of workmanship to which the public has long been accustomed. It provides brief biographies of some 40,000 living men and women, arranged alphabetically in 3,746 double-column pages. About a thousand entries have been deleted from last year's edition and replaced by the same number of new biographies, while many thousands of alterations and additions to existing entries have been made. *Who's Who* is an essential reference book in professional and business life, and the staffs of newspaper offices consult it every hour of the day. The publishers are A. and C. Black, Ltd., 4, Soho Square, London, W.1. The price remains at 60s. in buckram or 63s. in strong library binding with leather back; postage of a copy is 9d. inland, 1s. Irish Free State, abroad 1s. 10d.

Volume I of *Charterhouse Rheumatism Clinic Original Papers* was published last year by the Oxford University Press (price 15s.). It contains papers on pathogen selective culture and its bearings on the classification and aetiology of chronic rheumatic disease, by Dr. H. Warren Crowe; on the differential sedimentation test by Dr. Harry Coke; and on spondylitis adolescents with associated pathological changes in the sacro-iliac joints, by Dr. S. Gilbert Scott. Dr. Crowe explains in the preface that contributions here published are printed in the fullest possible detail, "so that there is no excuse for a failure by the technically capable worker to repeat the technique." Assuming sufficient support for this first volume, further research work (both now in being and planned) will be published in due course. The authors will be restricted to members of the staff of the Charterhouse Rheumatism Clinic in Weymouth Street, London, W.1.

Dr. R. M. B. MACKENNA has recently brought out a fourth edition of *Diseases of the Skin*, which was originally written by his father, and has taken the opportunity of bringing it thoroughly up to date. Like most textbooks it has increased considerably in size since its first appearance. It worthily maintains its place as one of the best textbooks of the subject in the English language. The illustrations, always an important feature in works on dermatology, are extremely good, and a special word of praise must be given to the coloured plates; there are no fewer than 46 of these, and most of them reach a high level of excellence. The numerous photographs in monochrome are also quite good. We can thoroughly recommend this book. It is published by Baillière, Tindall and Cox at 20s.

In *A History of Pharmacy* Mr. JAMES GRIER has produced within a small compass a thorough survey of his subject. He traces the evolution of pharmacy and the rise of the pharmacist from the earliest times of magical medicine through the period of the herbals to the scientific developments of the present day. A chapter is devoted to historical sketches of selected drugs, and the book provides all that is necessary for those who must satisfy the examiners in pharmaceutical history, which for examination purposes only begins in 1600. The general reader, however, will find much enjoyment in the earlier pages. It is interesting to read that in ancient Rome the universal remedies were garlic and cabbage (probably sea-kale), and that Virgil speaks of garlic and thyme refreshing the reapers. Also that the elder was one of the sacred trees of our earlier ancestors, and in folk-lore was the especial care of the queen of the elves or fairies. This book is admirably concise, and Mr. Grier is to be congratulated on compressing such a large quantity of information into so small a volume. It is published at 6s. by the Pharmaceutical Press.

Oral Diagnosis and Treatment Planning (W. B. Saunders, 25s.) has been written as a textbook for the dentist and as a work of reference for the medical practitioner. In his preface the author, Mr. KURT H. THOMAS, describes it as a master-key to diagnosis for the busy dentist, a reference-book for the physician, and a textbook on the technique of examination, diagnosis, and treatment planning. A complete diagnosis, he says, is frequently talked about but seldom taught in a systematic manner. The philosophy of treatment planning is discussed, but details of technique are left to the various clinical departments, lest, the author says, the work should become too encyclopaedic. The first few chapters deal with treatment planning, which means a review of the patient's general condition in relation to his dental condition; with oral and dental examination, x-ray examination, laboratory tests, biopsy, and the ethics of consultation. The larger part is devoted to diagnosis, and here the author proceeds somewhat on the plan of a well-known botanical handbook, *Name This Plant*. Diseases are grouped, according to their salient features, under

much of our pneumonia is amenable to serum treatment, and that we certainly cannot say; nor shall we be able to do so until typing is done far more frequently and extended to the individual types in Group IV. It must also be extended to cases of bronchopneumonia, since one fact which emerges quite clearly from American studies is that virulent pneumococcal infections amenable to serum treatment occur also in this variety of the disease. Such a study, if undertaken finally on such a scale as to apprise us fully of the pneumonia position in this country, could not be undertaken by any individual or in any single institution, or even by any self-constituted group of investigators; it demands the support and control of a public authority. What is involved if a serious effort is made to render serum treatment for pneumonia generally available may be gathered from a report by Cecil *et al.*,¹⁰ which reviews progress in this direction in the United States and makes recommendations for its extension. Such facilities exist at present only in the States of New York, Massachusetts, Connecticut, and Michigan, and they have been financed both by the State Government and by insurance companies and large charitable endowments. This service includes not only the provision of serum free of charge from numerous distributing stations but facilities for typing and an educational campaign directed to ensuring early diagnosis and immediate treatment.

It is emphatically stated at the conclusion of this report that the results already obtained justify the appropriation of State funds for this purpose. We have a long way to go in this country before such a position could be reached, since none of our serum, with the exception of that used by the London County Council, is yet produced by a public authority, though serum is distributed free to practitioners. Such an assumption of responsibility by public health authorities may or may not be desirable or necessary, but it is evident that, if anything needs to be done about pneumonia in this country, the problems both of investigation and of effective provision for treatment are quite beyond the capacity of individual effort.

EVALUATION OF DISABILITY

The growth of industry and of social insurance has given great importance to the question of the proper compensation of those who, by reason of accident or illness, are unable to earn a living, and whose diminished earning capacity needs to be supplemented by payments out of the various funds provided for this purpose. The International Labour Office has received many requests for advice on

how such disability ought to be assessed for the purpose of granting workmen's compensation, sickness benefit, and invalidity pensions. In November, 1936, the Office convened a meeting of experts in these matters, and commissioned them to prepare a report, in which the existing methods of assessment of disability should be reviewed and recommendations made as to how these methods might be improved. The committee entrusted with this work included representatives of Governments, insurance organizations, employers, and workmen, and its report has now been published under the title of "The Evaluation of Permanent Incapacity for Work in Social Insurance."¹¹ This provides an admirable survey of the practice of all the principal countries of the world in dealing with disabled persons.

Incapacity is considered in three aspects: loss of anatomical or physiological integrity; loss of ability to continue at work in the individual's own trade or in allied occupations; and general incapacity, including a consideration of such factors as the age, experience, and opportunities of the worker to obtain suitable employment. In many countries there is a schedule of injuries and other disabilities, to each of which is assigned a figure. This figure may be a percentage of average earning capacity, or a period of time estimated as representing the probable duration of incapacity for work resulting from such conditions, and it is used to fix the amount of money payable to the disabled worker. Such schedules are binding in some countries, while in others they are used only as a guide to the competent authority; it is suggested that the latter arrangement is preferable, and that when a schedule is used it should be reasonably comprehensive, should take account of the age and occupation of the worker, as well as of the nature of his handicap, and should be subject to revision from time to time, so as to conform to advances in knowledge and experience. In discussing the question of commutation of periodical payments by way of "lump sums," it is pointed out how this may prove unfair to the injured person if his condition should turn out to be disabling for a longer period than was expected at the time of settlement. It is not enough to rely on average periods of disability, for "there does not seem any justification for depriving an injured person whose incapacity proves to be lasting of all right to compensation on the grounds that other injured persons who have suffered a similar injury have been able to recover their earning capacity."

The problems involved in assessment of disability are exceedingly complicated, and include a con-

SERUM TREATMENT OF PNEUMONIA

The study of pneumonia has almost become the prerogative of workers in the United States, their efforts being followed and their results generally confirmed in this country on a much smaller scale and usually after a considerable lapse of time. This time-lag between the positions on opposite sides of the Atlantic now amounts to some five years, because much has happened in the United States since 1932 which has no counterpart here. It will be well to ask ourselves whether emulation of this work in this country would repay the necessary effort.

Recent developments in America may be summarized as follows. In the first place, the efficacy of serum treatment in infections due to pneumococci of Types I and II is established beyond doubt, and in certain States an elaborate organization exists to ensure that serum shall be available, free of charge, for every case of pneumonia requiring it. The results obtainable when the present-day concentrated serum is given really early in the disease are exemplified in a series of 160 Type I cases quoted by Cecil,¹ among which the mortality was only 5 per cent., while Cole² refers to a recent series of forty-seven similar cases in which there were no deaths. In this there is nothing radically new except the measures which have made the treatment available. The breaking of actually new ground began with Cooper's identification of new serological types among pneumococci previously described as of Group IV. That there were no fewer than twenty-nine of these newly defined types made it appear at first sight that their identification would be so complex as to be impracticable, but in some American centres it is now a matter of daily routine. Not only has the incidence of these numerous types in pneumonia been fully studied but the characteristic features of the disease produced by some of them have been defined, and in all of the nine new types so far studied from the therapeutic standpoint serum treatment has been found effective. Finland,³ for example, ascertained the type in 3,682 cases of pneumococcal infections, of which the

great majority were cases of pneumonia, and found examples of all the known types, although among those newly defined only V, VII, VIII, X, XIV, and XX occurred in substantial numbers (varying from ninety-three to 279 cases of each type); elsewhere⁴ he describes no fewer than 160 cases of pneumonia due to Type VII. Other extensive studies of pneumonia due to these types are those of Finland and Sutliff,⁵ who report 125 cases due to Type VIII, and of Rosenblüth and Block,⁶ who studied sixty-eight cases due to Type V: this type is said to cause a severe and prolonged attack, quite inconsistent with the common belief that "Group IV" pneumonia is a mild disease. Another recent and comprehensive study is that of Benjamin *et al.*,⁷ among whose 485 fully typed cases were considerable numbers of Types V, VII, and VIII; this paper is among those recording the results of serum treatment in some of the new types. A further innovation is the substitution of rabbits for horses as a source of serum. A useful account of this development is given by Horsfall *et al.*,⁸ who themselves prepared serum from rabbits and used it in twenty-two cases with only one death. Rabbits form antibodies to the pneumococcus more rapidly than horses and in greater amount, but the alleged superiority of rabbit serum may be due rather to the fact that the globulin molecule in the rabbit is only one-quarter the size of that in the horse (this fact has been proved both by ultra-centrifugation and by ultra-filtration); it may consequently be supposed to pass more readily through vascular endothelium, and has in fact been demonstrated in empyema fluids, whither it is said that horse protein cannot penetrate. Another advantage of serum production in rabbits is that the cost is only one-fifth of that involved in using horses. Whether this method will be generally adopted, as it certainly should if there is nothing to set against these remarkable advantages, it is still too early to say.

These are the facts from America. How do they affect us? The answer must largely depend on whether our pneumonia problem is similar to theirs. According to Horsfall⁹ there are 100,000 deaths annually from pneumonia in the U.S.A., of which it may be calculated from the known results of serum treatment that 35,500 are preventable. Pneumonia certainly has a lower mortality in this country than in the U.S.A.; whether it is also much less frequent—another belief which would furnish some excuse for our comparative inactivity—is doubtful. What really matters is how

Dr. F. A. Knott has conducted routine tests to determine the relative importance of hypersensitivity and bronchiolar infection in each case; and observations on rising sedimentation rate as an index of relapse, and on the effect of vaccines. At St. Mary's Hospital attendances are limited by providing the patient's general practitioner with material for treatment at home. The staff try to afford as much relief as possible to every patient who comes for treatment, holding that this method is not only philanthropic but also scientific, as it is the best means of obtaining the clinical material necessary for intensive investigation. Most of the research work has been done on hay fever, as it is convenient and deductions can be applied to other diseases of the asthma-urticaria group as well. All asthma patients tend to adopt a wrong way of breathing and benefit from remedial exercises. These are taught and their results investigated at King's College Hospital. In 70 per cent. of cases there is cure or considerable improvement, and only about 15 per cent. of those who acquire perfect breathing technique do not benefit at all. At St. Bartholomew's Hospital Dr. D'Silva has been working for a number of years on the mobilization of potassium in the blood after the injection of adrenaline. Blood sedimentation has been studied at the General Hospital, Birmingham. It would be a great pity if all this useful work were allowed to collapse for lack of funds.

WORLD REQUIREMENTS OF NARCOTIC DRUGS

The League of Nations has recently issued the estimates of world requirements of narcotic drugs for 1938 as formulated by the Supervisory Body under the Limitation Convention of 1931. These estimates have been furnished by 63 countries and 104 colonies or oversea territories. Where such information has not been vouchsafed in the case of some ten countries and as many colonies the Supervisory Body has itself framed the estimates. There is thus provided a conspectus for the whole world of the amounts of the several scheduled narcotics required for legitimate use. For morphine the total figure is 45,658 kilos, but of this only 10,126 kilos are for consumption of the alkaloid as such, the remainder being employed for conversion—for example, into codeine, heroin, or dionin. Of codeine the total is 29,921 kilos, of heroin 1,133 kilos, and of cocaine 5,032 kilos. In the case of morphine the requirement is rather more, and in the case of codeine considerably more, than it was in 1934, whereas the amount of cocaine required for legitimate consumption is less than for that year. Turning to the tables indicating the estimates furnished by the several Governments it is interesting to note that while the morphine requirement (including that for conversion) for Great Britain is 2,114 kilos, that for France is 4,650, for Germany 5,850, for Soviet Russia 8,000, for the United States 8,653, and for Japan 4,593. The requirements for heroin in kilogrammes are: Great Britain 56, Germany 3, Soviet Russia 350, United States 0, and Japan 180. The highest estimates for heroin for use as such were received from Soviet Russia, Italy,

and Japan. The consumption of cocaine appears to be greatest in Japan, the United States, and Soviet Russia. The countries which failed to furnish the required estimates and for which the Supervisory Body itself had to frame them were Mexico, Cuba, Panama, Ecuador, Paraguay, Peru, Bolivia, Ethiopia, Liberia, and the Union of South Africa.

A NEW FOOD AND DRUGS BILL

Publication of the third interim report of the Local Government and Public Health Consolidation Committee marks a further step in the consolidation of the public health law. The report (Cmd. 5628, price 1s.) is accompanied by a draft Bill (Cmd. 5629, 1s. 6d.), and deals with the law relating to food and drugs. It also extends to markets and slaughterhouses. The committee was set up in 1930 by Mr. Arthur Greenwood, then Minister of Health, under the chairmanship of the late Viscount Chelmsford, who was succeeded by Lord Addington, the present chairman. Its original terms of reference were:

With a view to the consolidation of the enactments applying to England and Wales (exclusive of London) and dealing with (a) local authorities and local government and (b) matters relating to the public health, to consider under what heads these enactments should be grouped in consolidating legislation and what amendments of the existing law are desirable for facilitating consolidation and securing simplicity, uniformity, and conciseness.

The existing law relating to food is directed towards two distinct objects—the safeguarding of public health and the protection of purchasers from fraud and deception—and, while in the main the public health code deals with the first of these objects and the sale of food and drugs code with the second, the legislature has not been entirely consistent and there are many provisions of a public health character in the latter code. The committee felt that, as a matter of practical convenience, the two codes should be combined in a single measure; and for this purpose its terms of reference were enlarged. For reasons indicated in the report the draft Bill, unlike the two earlier local government and public health Bills prepared by the committee, extends to London. For this purpose also the committee's terms of reference were enlarged and its membership increased so as to secure representation of the London authorities. The draft Bill, in addition to securing this unification of the two existing codes, represents a great simplification of the existing law. Its 102 clauses take the place of some 240 sections of existing Acts, some of which, dealing with the adulteration of tea and coffee and with knackers' yards, date from the eighteenth century, and others, such as the Bread Acts, from the early nineteenth. Of the more modern Acts reproduced in the draft Bill mention may be made of the Milk and Dairies (Consolidation) Act, 1915, the Milk and Dairies (Amendment) Act, 1922, the Artificial Cream Act, 1929, the Public Health (Cleansing of Shell-fish) Act, 1932, and the Milk Act, 1934. The changes which the Bill would effect are dealt with in detail in the report and an appendix. Among the more important may be

sideration of medical, industrial, economic, and legal factors. Such problems cannot properly be dealt with except by an authority which is so constituted as to be able to give due weight to all these factors. In practice the authorities may be classified under three heads: (1) civil courts, (2) accident or invalidity insurance institutions, (3) special courts or boards set up for the purpose. There is much to recommend the last-named of these, provided that the tribunal is representative of all the interests which should be concerned. Experts may be attached to such an authority, either in an advisory or a judicial capacity. The report discusses the safeguards which should be provided to ensure that the assessment shall be made with proper impartiality, full knowledge of the facts, and reasonable dispatch and economy, and the point is made that there should be arrangements for appeals and for a review of the case if necessary. This report is a well documented and most helpful contribution to a subject which is likely to be of increasing importance with the expansion of industrial medicine.

INDUSTRIAL POISONING

The steadily increasing importance of organic chemistry is one of the outstanding features of modern industrial development, and new compounds are continuously being introduced for use both in factories and in our homes. The extent of this development is revealed by the report issued by the Medical Research Council on *Toxicity of Industrial Organic Solvents*,¹ which describes no fewer than one hundred of such compounds. This figure is a tribute to the enterprise of industrial chemistry, but at the same time is somewhat alarming from the point of view of industrial hygiene. The great majority of these compounds are volatile, and hence those using them are likely to be exposed to their fumes, even though this risk is greatly reduced in modern plants. On the other hand, our knowledge of the toxic actions of drugs on man is very limited; indeed few would care to prophesy whether a new compound is harmless even as regards the production of acute poisoning, and this lack of knowledge is even more pronounced as regards the risk of chronic forms of intoxication, because the estimation of minor toxic disturbances due to prolonged exposure to low concentrations of vapour is such tedious and difficult work that it is unlikely to be undertaken except in institutes specially equipped for the purpose. For such reasons knowledge of the pharmacological actions of new chemicals has been apt to lag far behind their industrial application. There is a tendency, therefore, for the toxicity of new solvents to be determined by the simple method of large-scale trial upon human populations. The dangers of such a situation are obvious, and we must consider it a fortunate chance that hitherto we

have had relatively few unpleasant surprises regarding the toxic potentialities of new compounds. The report of the Medical Research Council represents a step forward, since it collects in one volume such knowledge as is at present available. Study of the volume brings to light the remarkable variety of substances used as industrial solvents, and it shows too that the information concerning their actions on animals and man is scattered throughout an extremely wide range of literature. The mere collection of this widely dispersed material is an important first step in the advance of knowledge of the properties of these important compounds, whose use is now extending so rapidly. Examination of the evidence collected shows, however, that in most cases it is very incomplete, a fact emphasized in the introduction to the report. There is thus an urgent need for the organization of systematic research on this subject, so that pharmacological knowledge may be kept more nearly abreast of the advances made by organic chemists; otherwise it seems inevitable that sooner or later some really dangerous substance will find its way into industry and do much harm before its potentialities for evil are recognized.

PROGRESS IN ASTHMA RESEARCH

The Asthma Research Council makes grants to qualified investigators who work in asthma clinics and in laboratories attached to hospitals. The money is derived almost entirely from donations, but a small part of the revenue comes from the sale at 1s. a copy of the useful booklet *Physical Exercises for Asthma*. Last year the Council published a second and revised edition of this pamphlet, which, with the annual report for 1937, may be obtained from the Secretary, c/o King's College, Strand, London, W.C.2. The report, which is sent to inquirers free of charge, gives ample evidence of valuable work, but also stresses the need for a constant supply of money. Owing to lack of funds the Council could not give further grants to the clinic at Leeds General Infirmary or to the St. John Clinic, Pimlico, or continue to pay for research in "wide-field" x-ray therapy. It will have to reduce its expenditure still further in the new year unless the work receives the support it deserves. Interesting results have been obtained at the Guy's Hospital clinic and will be published shortly. Of thirty-five cases treated by protein inhalation for rhinorrhoea fourteen showed either cure or considerable improvement, five some improvement, and sixteen none. Considering how intractable these cases are the figures are encouraging. Attention is being turned from groups to individual cases; patients are admitted for biochemical investigation, and an allergen-free room has just been made available. Dr. Gerson has been treating some particularly obstinate cases by diet, and Dr. Strauss has investigated the psychogenic factor.¹ Dr. Bruce Pearson has completed a paper on his investigations into skin sensitivity, which showed that a surprising number of apparently normal people give positive skin reactions to common inhalants.

¹ See page 73 of this week's issue.

the bacteriology of water supplies, milk, and food infections; on Dr. Charles McMoran Wilson, a London physician whose fine work as Dean of St. Mary's Hospital Medical School must be known to all readers of this *Journal*; and on Dr. Charles Norman Paul, dermatologist to the Sydney Hospital. Lord Nuffield's princely benefactions to medicine and other good causes are rewarded by a viscountcy, and Mr. E. W. Meyerstein's large gifts to hospitals and medical schools by a knighthood.

EVERYDAY PROBLEMS OF INCOME TAX

The statutes concerning income tax have become notorious for their complexity, as indeed the report of the recent Codification Committee frankly admits, and the authors of a recent handbook¹ set themselves no mean task when they proposed "to deal with everyday problems in ordinary everyday language." They have succeeded to a very commendable degree, and in so doing have supplied a want which is often felt, and which has sometimes been expressed in letters to the editor of this *Journal*. The binding, print, and general arrangement are particularly good for a book published at a low price, and the contents can fairly be claimed to cover the "everyday problems," and a good many more that are less frequent but nevertheless common enough to justify inclusion in a general statement of the law and practice of income tax. The professional man will find such questions as beginning and ceasing practices, and successions clearly dealt with; and there is a chapter on the allowances for depreciation, renewal, and obsolescence of machinery, which is very well written. A pleasing feature of the book is the frequent use of clear and simple examples, without which, indeed, verbal explanation of such matters is always difficult to follow. There are one or two points which the authors might usefully reconsider for a second edition. Thus their remark that allowable advertising expenditure includes "the reasonable entertainment of customers" is perhaps literally true, but would be incorrect if "customers" were read as including professional clients. The chapter on salaried employments, etc., would have been improved by the addition of a note on the concessional practice of including the emoluments of a medical office as part of general practice receipts. As the chapter stands it implies that all such salaries must be separately assessed under Schedule E, whereas the reverse is not only the common but also the much more convenient course. The "Notes on Accounts" in Appendix A include an example of the account of a medical partnership which should be helpful, and there is a useful note on the cash basis account, or, as the authors call it, an account "on a receipts and payments basis," in which they express the opinion that "there is a growing reluctance on the part of the Revenue authorities to agree to accounts drawn up on this basis, when presented for the first time." In our experience such reluctance can usually be overcome, assuming that accounts have been

supplied for, say, the first three years on the earnings basis. We disagree definitely with the authors on one point arising out of the "cash basis." They regard with favour the practice of adding the amount of the outstanding book debts to the profit shown by a cash basis account for the final year of a practice. We regard such an addition as incorrect, and unfair to the practitioner. It should be assumed that the profits of the first three or four years of the practice have been assessed on the earnings basis, and the fact that the profits so calculated exceeded the cash profits of those years provides a sound reason for adhering to the amount of the cash basis profits when the practice is treated as having ceased. This, however, is a minor blemish on one of the most successful attempts we have yet seen to state income-tax practice simply, clearly, and in a readily accessible form.

CALCIUM DEFICIENCY

The article in our present issue (p.59) by Dr. Katharine Coward and her co-workers provides interesting information about the effect on young rats of a "normal" poorer-class diet consisting largely of bread, margarine, jam, and potatoes, with some meat and a little milk and green vegetables. One series of experiments was devised to check the conclusions of Simpson and Wood,¹ who found, with children of the poorer class, that addition of virol to the diet produced more benefit than did addition of either cod-liver oil or of halibut-liver oil plus dried milk. The experiments on rats gave the opposite result, since the liver oils produced beneficial effects, while the virol was almost without influence. These two series of conflicting results are so unlike in character that it is difficult to estimate their relative importance. It is, of course, obvious that experiments on rats provide only indirect evidence regarding the dietary requirements of children. On the other hand, it must be remembered that a standard of accuracy is possible in animal experiments that is completely unattainable in feeding experiments with children. A second series of experiments made with young rats fed on the "normal" poorer-class diet described above, with the addition of cod-liver oil, showed that the percentage of ash in their bones was slightly less than four-fifths that of the normal. The addition of cod-liver oil should have ensured the absorption of the calcium and phosphorus present in the diet; moreover, the deficiency in bone ash was prevented by the addition to the diet of either a salt mixture containing calcium and phosphorus or milk. The authors conclude: "This proves quite clearly that the ordinary mixed diet of the poorer classes is seriously deficient in the elements required for the calcification of bone." The importance of this conclusion is so obvious that it requires little comment. It is in general accordance with the findings of American authorities such as Sherman, who have contended for many years that calcium deficiency is one of the most serious dangers of improperly balanced diets.

mentioned the alteration in the definition of "Food and Drugs Authorities"—that is, the authorities to be entrusted with the administration of the provisions of the Bill dealing with the adulteration of food and drugs. The course recommended by the committee and given effect to in the draft Bill is to abandon the present definition, which is based on factors some of which are plainly out of date, and to include in the definition county councils and county borough councils (as at present) and councils of non-county boroughs and urban districts having a population of not less than 40,000 with a discretionary power for the Minister of Health to confer the functions on the council of any other borough or urban district with a population of more than 20,000. The committee has not considered its task to be the framing of ideal legislation, but has attempted to reproduce the existing law with such amendment only as in its opinion would be likely to command general assent.

SUICIDE IN AMERICA

Suicide is becoming recognized in the United States and also in Canada as a serious sociological problem. One of the most recent surveys comes from Boston, where Dr. Merrill Moore has published¹ an account of the 1,147 patients who were admitted to the Boston City Hospital between the beginning of 1915 and the beginning of 1936 after attempting suicide. He finds that attempted suicide cases are coming to the hospital in greater numbers: 99 cases in the last year of the period against 24 in the first. The sex incidence was fairly equal: 616 women and 531 men. Seventy-two men and 55 women succeeded; perhaps, Dr. Moore thinks, men generally use mechanical and more physically aggressive methods, such as shooting, slashing, and leaping, whereas women usually take poison. The most popular methods in order of choice were poison by mouth, inhalation of gas, cutting throat or wrists, leaping, shooting, hanging, and drowning. The great majority were discharged "relieved." Only 67 patients were obviously ill enough in mind to be sent to a mental hospital. The age distribution definitely related suicide to the curve of sexual activity: the largest age group in women was 20-25, in men 26-30. The motives, among the 266 patients who stated them, were chiefly economic factors in the men and domestic difficulties in the women, ill-health coming third in both. About 10 per cent. drank alcohol shortly before or at the time of the attempt. No fewer than 322 patients drank iodine, but none died; the next most popular poisons were mercury compounds, barbiturates, "syphonathol," and mercurochrome. So far as could be ascertained few patients repeated the attempt. Married women made the largest status group with 260, then unmarried women 176, married men 163, and unmarried men 148. Unemployment appeared possibly to be a precipitating factor: 50 per cent. of the women were not lucratively employed. Among the employed an important predisposing factor seemed to be maladjustment to their work. Few attempts were made in the

winter; the favourite month for men was April and for women August, the favourite day for men Sunday and for women Wednesday. Most of the patients were white and came from the lower classes. Dr. Moore suggests that more individual attention should be paid to failed suicidal cases, especially from the point of view of psychology and of social medicine. He proposes the establishment of protective wards in large general hospitals where patients may be treated and studied. From Toronto Dr. Ruth Franks,² who has studied 352 consecutive cases of attempted suicide admitted to the Toronto City Psychiatric Hospital from November 1, 1928, to October 31, 1935, suggests that suicide may be prevented by raising the standard of education and the mental and physical health of the populace, by teaching certain lay and professional groups to recognize the danger signals of probable suicide; by abolishing the stigma, minimising publicity, fencing off heights, and paying greater attention to suicide in medical, social, and legal instruction. She also considers that improvement may result from training young persons to take responsibility and from encouraging the cohesion of social groups. She lays stress on the value of a fixed regular routine day in bringing satisfaction and contentment to unsettled persons, and also advocates clinics to which those who are distressed may come for help. She finds a higher incidence in foreign-born than in native persons, and considers that this difference should be investigated. Rather surprisingly, she does not suggest any means for improving the economic position of would-be suicides, perhaps because the problems which this cause involves are too large and difficult for the scope of her thesis.

THE HONOURS LIST

A classified record of the medical New Year's Honours, taken from the *Supplement* to the *London Gazette* of December 31, will be found at page 88. The outstanding item in the eyes of members of the British Medical Association is the knighthood conferred upon our President, Professor Robert James Johnstone. The success of the Annual Meeting at Belfast last year was largely due to his genial personality and the commanding position he holds in the medical profession and the public life of Northern Ireland. The Right Hon. Earle Page, Minister of Commerce and Deputy Prime Minister of Australia, whom we welcomed in this country not many months ago, receives the high honour of G.C.M.G., and Lord Horder that of G.C.V.O. Major-General Ernest A. Walker, I.M.S., lately Director of Medical Services in India, Army Headquarters, becomes K.C.I.E.; and Miss Florence Barrie Lambert, well known for her work on the London County Council, is created D.B.E. The honour of knighthood is conferred also on Dr. Joseph William Leech, M.P. for the Newcastle-on-Tyne West Division and a former Lord Mayor of Newcastle; on Dr. William George Savage, who has now retired from the post of county medical officer of health for Somerset after twenty-eight years' service, during which he published valuable reports on

be applied if the upper limb is involved, and in the case of the trunk or lower limbs confinement to bed for a few days is desirable, except in the mildest cases. A detailed description of the treatment of cellulitis is beyond the scope of this article, but the frequent application of hot hypertonic saline solution (1/2 oz. of salt to 1 pint of water) by means of either immersion or hot compresses is an excellent method of treatment. Abrasion of the knees in children ("gravel rash") is not uncommonly followed by some degree of cellulitis, which is apt to result in a sympathetic effusion into the knee-joint. Doubt may exist as to whether the effusion is serous or purulent, but in the former case a few degrees of painless movement is possible, whereas suppurative arthritis causes intense spasm, and severe pain is experienced at any attempt to move the joint. If a diagnosis cannot be made in any other way a needle should be inserted through healthy skin and a small quantity of fluid withdrawn for examination. In the case of inflammation following an abrasion giving rise to adenitis of the regional lymphatic glands the timely application of antiphlogistine or kaolin tends to avert suppuration. The general health must also receive consideration, sedatives, aperients, stimulants, or tonics being ordered as necessary. If the infection is streptococcal in nature, then sulphanilamide should be prescribed.

Abrasions of Special Organs

Abrasions of the alimentary canal are worthy of mention; scratches or abrasions due to a fish-bone or other sharp object are common events in general practice. The patient usually insists that the sharp object is still *in situ*. If he locates the site of injury to the mouth or pharynx a careful inspection must be made, in order to confirm its presence or else to disprove his statement and reassure him. Special attention is paid to the tonsillar fossae, as a small fish-bone embedded in the tonsil is readily overlooked. If the patient says that a small foreign body is "sticking in the gullet" he should be reassured and directed to feed on pulqueous food, and it may be justifiable to prescribe some harmless medicine or a mild bromide mixture as a placebo for a nervous patient. If the symptoms persist for more than twenty-four hours an oesophagoscopy should be performed, as the patient may be correct! I have seen death result from ulceration of a fish-bone through the wall of the oesophagus into the arch of the aorta, and cases of mediastinitis are occasionally reported. The old-fashioned probang should not be used unless it is impossible to obtain the services of a surgeon familiar with oesophagoscopy. A cotton-wool sandwich may be of assistance occasionally. A thin layer of cotton-wool is sandwiched between two pieces of well-buttered bread, and the patient is asked to eat this. Some of the cotton-wool does tend to collect round the fish-bone or other foreign body, and may diminish the possibility of its injuring or penetrating the gut. Occasionally abrasions of the other end of the alimentary canal are also fraught with danger. An enema syringe with a rigid nozzle should never be used unless a rubber catheter is attached, otherwise it may abrade or even perforate the wall of the anal canal or rectum. Such abrasions have been followed by cellulitis of the wall of the bowel, which in some cases has spread to the pelvic cellular tissue with fatal results.

Abrasions of the cornea always require careful attention so as to avoid the development of a scar, which, if situated centrally, will impair vision, and in any case will persist as an ugly reminder. Two or three drops of castor oil and a pad and bandage for twenty-four hours is usually

adequate treatment. Lead lotion should never be applied to skin abrasions in the region of the orbit unless it is quite certain that no corneal abrasion exists, otherwise lead albuminate forms over the abraded area and remains as a permanent corneal opacity.

Contusions

The term "contusion" implies laceration of and haemorrhage into subcutaneous tissues or deeper structures, following an external injury but unassociated with any wound of the skin. The clinical features of a subcutaneous contusion are pain, which occurs immediately, ecchymosis, which follows shortly, and swelling, the extent of which depends upon the severity of the injury and the laxness of the damaged tissues. Pain varies with the extent and site of the injury. Contusion of tissues which can accommodate a considerable extravasation of blood, such as the scrotum, is comparatively painless, whereas a contusion of the auricle is usually somewhat painful. Ecchymosis, or bruising, is due to infiltration of the tissues with blood, and if extensive the overlying skin may be almost black in colour. This is especially noticeable when the injury affects lax tissues in which oozing readily occurs, as, for example, when injury to the circumorbital region results in a "black eye." In some cases the blood extravasates along the fascial planes and appears at a distance from the site of injury; thus, a blow on the skull is apt to damage subaponeurotic vessels, and bruising may appear some days later in the eyelids or in the region of the mastoid process.

In the case of severe contusions a haematoma may form and present itself as a fluctuant or boggy swelling. As a rule serum collects in the centre while fibrin is deposited in the periphery, and eventually the haematoma is absorbed. At this stage a subpericranial haematoma closely simulates a simple depressed fracture of the vault, as on palpation the edge of the clot resembles the rim of bone surrounding a depressed area of the skull. However, the clot can sometimes be indented by the finger-nail, and in the absence of intracranial complications delay of a few hours is of little moment, so a radiograph can be taken in order to distinguish the two conditions. Occasionally a haematoma persists as a permanent swelling, which consists of a sac containing serous fluid and surrounded by laminated fibrin, which later is organized into fibrous tissue. Haematoidin crystals, derived from blood pigment, are commonly found in the wall of this so-called "blood cyst." If the history of injury is forgotten by the patient a blood cyst is a fruitful source of errors in diagnosis.

A common complication of contusions, associated with either extravasation of blood or a haematoma, is infection. The organisms gain entry either through a coexisting abrasion, or are blood-borne from some focus of infection such as the tonsils or teeth, or from distant cutaneous lesions. The advent of suppuration is indicated by increased swelling, heat, and constitutional disturbances. The swelling associated with a contusion is due primarily to oozing from small blood vessels. The blood which escapes subsequently clots and excites an aseptic inflammatory reaction. If the nutrition of the underlying skin is impaired thereby blebs or blisters are apt to develop, a condition which not infrequently complicates the treatment of fractures of the tibia.

Treatment of Contusions

The treatment of a contusion is directed first of all towards limiting the amount of oozing from ruptured

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

ABRASIONS AND CONTUSIONS

by

R. J. McNEILL LOVE, M.S., F.R.C.S.

An abrasion as such is of little moment, but it may be of supreme importance in that solution of continuity of skin or mucous membrane is apt to allow the entry of organisms into the tissues. Theoretically even the smallest abrasion should be treated with promptitude, and treatment maintained until the wound is soundly healed. In practice, however, small abrasions are often considered to be such trivial injuries that they are apt to be neglected, or at the most receive a "dab of iodine." Members of the medical profession who are exposed to the risk of virulent infections, especially pathologists and surgeons, are sometimes sufficiently careful to protect an abrasion from infection, but even among our own profession tragedies occur from time to time. The organisms which may gain entry through an abrasion fall into two groups—namely, non-specific, or pyogenic, and specific.

Non-specific Infections

Various strains of staphylococci and streptococci commonly affect the tissues in the region of a neglected abrasion. Staphylococcal infections are usually localized, and if suppuration occurs the pus is thick and creamy. Streptococci, on the other hand, are apt to cause a rapidly spreading inflammation, and any pus which may form is scanty in quantity and seropurulent in nature. It is of importance, especially in connexion with treatment, to remember that organisms which have gained entry through an abrasion may spread by any of the following routes: (1) by continuity, which mode of spread is most in evidence when virulent organisms, especially streptococci, infect loose connective tissue, such as the subaponeurotic space under the scalp, or subcutaneous tissues; (2) by lymphatic channels, when red streaks may be seen denoting acute lymphangitis, going on to enlargement and tenderness of the regional lymphatic glands, which may subsequently suppurate; (3) by the blood stream, some degree of toxæmia being expected if the infection is of moderate severity, while if the invading organisms are virulent or the resistance of the patient is low, septicaemia may follow, or even pyæmia with associated metastatic abscesses.

Specific Infections

Probably the specific organism most to be dreaded is the *B. tetani*. Abrasions contaminated by cultivated soil are particularly dangerous, but those associated with street accidents are less prone to be infected with tetanus than formerly, owing to the diminishing numbers of horses now employed. Nevertheless, any patient who has sustained an abrasion of sufficient depth or so contaminated as to be potentially infected must be given an intramuscular injection of 1,000 international units of anti-tetanus serum. Some calcium preparation should be given orally for a few days, so as to prevent or minimize serum reaction—this applies to the administration of any serum. Among the other specific organisms which may gain entry through an abrasion is the *Spirochaeta pallida*. Prophylactic treatment, such as washing with potassium

permanganate solution, 1 in 1,000, and the subsequent application of 30 per cent. calome! ointment, practically guarantees freedom from infection.

Hydrophobia is due to infection of an abrasion, usually at the time of infliction, but occasionally inoculation follows the licking of an abraded area by an infected animal. If infection is suspected the wound should be treated immediately by the actual cautery, or by a strong caustic such as pure carbolic acid, which is less painful owing to its local anaesthetic properties. If reasonable grounds exist for presuming that the offending animal was suffering from rabies, then the patient is sent without delay to an institute where he can receive Pasteur treatment. As the incubation period in man is rarely less than two months, ample time is available for the journey to a recognized centre.

The anatomical tubercle (verruca necrogenica) is a further example of the danger of inoculation of an abrasion. This condition occasionally occurs in butchers and others who are exposed to inoculation by tubercle bacilli. A warty excrescence presents itself, usually on the back of the hand. The most expeditious treatment is by excision.

Treatment of Abrasions

An abrasion should be treated by suitable dressings until it has completely healed and all risk of infection has disappeared. This applies particularly to patients who are exposed to irritants, such as chemical workers, and to medical practitioners, nurses, or undertakers, whose occupation subjects them to the risk of inoculation by organisms. During the first few hours, when the abrasion is still clinically uninfected, the application of a mild antiseptic is all that is required locally. Tincture of iodine (B.P., 2½ per cent.) is commonly applied as a first-aid expedient, but such a strong antiseptic is liable to do more harm than good, as it devitalizes the tissues and renders them less resistant to infection. This is especially so in those cases in which a few hours' delay has allowed organisms to enter the wound. Therefore, except possibly as an immediate application to a small abrasion, tincture of iodine is not to be recommended. More suitable applications are surgical spirit, aqueous solution of flavine (1 in 1,000), or eusol, which must be fresh and applied cold. The antiseptic property of eusol depends mainly upon the presence of chlorine, which is readily driven off if the solution is heated. Other suitable antiseptics are lysol, and its allied preparations, in 1/2 per cent. solution, or dettol. Friar's balsam (tinct. benzoini col.) is a popular and efficient application. Any of these antiseptics, except eusol, is applied once or twice daily. A eusol dressing should be changed three times daily, as its antiseptic properties rapidly deteriorate. If the abrasion is contaminated with soil, gravel, or dirt an anaesthetic is sometimes desirable, so that the wound can be thoroughly cleansed and ragged skin removed, or the edges excised. A general anaesthetic is usually required for children, and in the case of adults evipan or an allied preparation is very satisfactory.

If infection develops treatment is directed to localizing the inflammation, as a spreading cellulitis may cause a long and anxious illness and even terminate fatally. The first essential is rest to the affected part. A sling should

Nova et Vetera

EDINBURGH ROYAL INFIRMARY

DR. LOGAN TURNER'S HISTORY

Few persons are better qualified to write the history of the Edinburgh Royal Infirmary¹ than Dr. Logan Turner. He was educated there, was house-surgeon to Mr. Annandale, served his term of office as surgeon to the ear, throat, and nose department, and is widely read in the history of medicine. He has had access to the minute-books of the Infirmary, and the volume may be looked upon as both accurate and readable. The first few chapters are devoted to the foundation of the medical school at Edinburgh. Dr. Logan Turner traces the persistence of the Hippocratic tradition, showing how it was kept alive in Europe and how in due course it came to Edinburgh. Clinical teaching was always one of its features. Boerhaave made it fundamental at Leyden, and from Leyden it was brought to Edinburgh in the middle of the eighteenth century. Teaching in the presence of the patient was a novelty. It quickly attracted students from England, Ireland, the American colonies, and the dependencies, and the Edinburgh school of medicine thus became famous throughout the English-speaking world.

"The Little House"

From the foundation of the medical faculty in Edinburgh University Dr. Logan Turner passes to the history of the Royal Infirmary. It began humbly in 1729 as a voluntary effort to relieve the sick poor coming from any part of Scotland—"The Little House," with only six to eight beds, under a mistress at a salary of £4 sterling and one servant. Thirty-five patients were admitted the first year, with nineteen cured and one death, at a cost of £97 19s. 7½d. The money was obtained in part by an "Infirmary Sunday," when the General Assembly of the Church earnestly recommended that all the parish churches throughout Scotland should set aside a Lord's Day on which a collection should be taken up. "The Little House" was to be staffed only by Fellows of the Royal College of Physicians of Edinburgh on a fortnightly rota of service, a system which was soon proved to be unworkable. Within a short time it was found necessary to have surgeons; two were chosen, each to act for a month at a time, operate, and supply medicines gratis. Students availed themselves of the teaching at the hospital, and arrived in such numbers as to be embarrassing both to the staff and to the patients. The remedy was to enforce a payment of two guineas for the privilege of "walking the hospital," the money being allocated to the general funds of the Infirmary.

The advantages of a hospital were recognized, a Charter was granted, and arrangements were made for a building to accommodate 228 patients. This was found to be on too grand a scale, and when it was opened in 1741 the "family" to be transferred from the old quarters consisted only of thirty-four patients. During "the '45" until after the battle of Culloden the Infirmary was practically a military hospital, and the sum of 4½d. to 7½d. a day was paid for each soldier. In 1918 the cost per soldier had risen to 4s. 9d. a head, with an allowance of sixpence a day for each unoccupied bed placed at the disposal of the military authorities.

¹ *Story of a Great Hospital. The Royal Infirmary of Edinburgh, 1729-1929.* By A. Logan Turner, M.D., LL.D., Hon. F.R.C.P. Ed. (Pp. 406; 34 illustrations, 4 plans. 10s. net.) Edinburgh: Oliver and Boyd, Tweeddale Court. London: 33, Paternoster Row, 1937.

Teaching and Staffing

The history explains how there arose the system of teaching partly by a professorial staff and partly by the ordinary staff of the hospital, which *longo intervallo* has now been adopted by the "units" in many of the English voluntary hospitals. It tells, too, of the rise and growth of the nursing staff, and gives a very excellent portrait of Nurse Janet Porter, of whom W. E. Henley wrote:

"The doctors love her, tease her, use her skill;
They say 'The Chief' himself is half afraid of her."

She was perhaps the last of the system which placed a staff of nine women in charge of seventy-two patients, distributed in six wards and six little rooms, whose wages in 1792 were raised from £3 10s. to £5 per annum. They worked magnificently, but in later days shared, quite undeservedly, the opprobrium which was justly due to the "watchers." Women who were not resident in the Infirmary came in at night and were paid from fourpence to sixpence for each attendance. The battle of women to secure medical teaching is described at length, due credit being given to Miss Jex-Blake and Mrs. Garrett Anderson. They were helped amongst others by Patrick Heron Watson, who taught them surgery from eleven to midday every Sunday until complaint was made, when he moved the time of his class forward to nine o'clock so as not to interfere with the hour of Divine service.

The history is continued until the present time, and shows how the different special departments have developed, adding greatly to the usefulness and advancement of medical science. Finally there are appendices recording various data which it would be difficult to obtain otherwise. There is a good index, and the illustrations are remarkably well reproduced. On the whole this is a most useful and very cheap book, for it only costs ten shillings.

D'A. P.

ANNALS OF MEDICAL HISTORY

The frontispiece of the September number of the *Annals of Medical History*¹ reproduces the comfortable result of laughter and what often precedes it as shown by the figure of Sir Theodore Turquet de Mayerne, the first Fellow of the Royal College of Physicians of London to be chemically minded. Dr. P. Gibson of Kingston, Ontario, sketches the life of this fine clinician and court physician of the seventeenth century, and publishes some of his letters. Dr. J. T. Howard of Baltimore writes on the Doctors Gustavus Brown and, by his reference to the three traditional explanations of Gustavus as a family name, supplements Dr. Eugene Cordell's account in 1902 of "The Doctors Gustavus Brown of Lower Maryland." Vesalius's description of the vermiform appendix under the name of the "blind intestine" is reproduced by Dr. Samuel W. Lambert of New York, and thus explains the authoritative statement that Vesalius did not mention the vermiform appendix, though it appears in Calcar's illustrations in the *De Fabrica*. In his article on Nathan Smith and early American medical education Dr. L. D. van Antwerp quotes the pleasant simile of W. H. Welch: "Nathan Smith's essay on typhus fever is like a fresh breeze from the sea amid the dreary and stifling writings of most of his contemporaries." The life of Jean Dominique, Baron Larrey, Napoleon's fearless surgeon, is sketched by Dr. P. E. Bechet, who provides illustrations of his "flying" ambulance and his handwriting. Two articles continued from previous instalments—"The Doctor on the Stage" and the "Medical History of Vienna"—are concluded in this number.

¹ *Annals of Medical History.* New Series, Vol. 9, No. 5, September, 1937. Edited by Francis R. Packard, M.D. (Pp. 401-516; illustrated. £2 10s. for volume of six numbers. New York: Paul B. Hoeber, Inc., Medical Book Department, Harper and Brothers. London: Baillière, Tindall and Cox.

capillaries and small vessels, and so controlling the extravasation of blood and preventing the formation of haematomata. The first essential is again rest to the affected part, either by the limitation of activities, splinting, or confinement to bed. The application of cold in the form of an ice-bag or suitable lotions, such as lead lotions or surgical spirit, is valuable. The traditional raw beef-steak for contusions of the orbit is an example of a cold application. In some cases pressure by means of a bandage, perhaps soaked in cold water, will limit extravasation, but care must be taken not to interfere with the circulation of the affected part.

The majority of haematomata require no surgical intervention, but a timely incision is occasionally needed to relieve tension and evacuate blood clot when a contusion results in the extravasation of the blood or the formation of a haematoma in a confined space. A classical instance is contusion of the muscles of the forearm, which are enclosed in an inelastic fascial compartment. Extravasated blood causes an abnormal tension in this confined space and consequent impairment of venous circulation. Neglect or delay in incising the deep fascia of the arm may cause lifelong disability in the form of Volkmann's ischaemic contracture. In some situations an ugly mass of organized blood clot is apt to persist if the haematoma is treated conservatively—the "cauliflower ear" which follows an untreated contusion of the auricle is a good example. This can be prevented by a small incision, evacuation of the serum and recent clot, and the application of a firm elastoplast dressing.

Contusions of deeper structures, such as the brain or lung, are beyond the scope of this article, but a few words may be added in connexion with the abdominal organs. A contusion of the liver is suspected rather than actually diagnosed. The site of injury, possible association with a fracture of the lower ribs on the right side, a moderate degree of shock, and local tenderness all suggest the nature of the injury. A constant pulse reading indicates that progressive haemorrhage is not occurring, and two or three days later suspicions of a contused liver are sometimes confirmed by the appearance in the urine of bile, which has escaped from ruptured biliary capillaries and which is subsequently absorbed by the blood stream. Very occasionally a circum-umbilical patch of jaundice appears, due to the extravasation of bile into the cellular tissue overlying the bare area, and absorption of bile pigment by the lymphatics which accompany the ligamentum teres. The treatment of a suspected contusion of the liver is expectant; omnopon is given (morphine is unnecessary in the absence of severe pain, and is apt to cause vomiting and alimentary derangement) and an ice-bag applied over the site of injury. A careful watch is kept on the pulse, so that continued haemorrhage may be readily recognized, and more energetic treatment instituted if necessary.

Contusion of the kidney is diagnosed by haematuria following trauma in the kidney region, and occasionally an indefinite swelling is palpable in the loin, due to extravasation of blood and urine. Every specimen of urine should be saved and compared with previous ones, so that some idea can be gained as to whether the bleeding is subsiding or persisting. Omnopon is given and an ice-bag or cold pack applied to the renal region. Urinary antiseptics are said to prevent the development of a perinephric abscess, which is a common complication of a contused kidney. If haematuria is persistent, or if the pulse rate rises, operative intervention should be considered, in order either to repair or remove the kidney.

CONGRESSES ON RHEUMATISM AND HYDROLOGY

The Oxford Meeting

The International Congress on Rheumatism and Hydrology, which is to be held in Oxford, with preliminary entertainment in London, from March 25 to 31, is being convened jointly by the International Society of Medical Hydrology and the International League against Rheumatism.

The president-elect is Sir Farquhar Buzzard, Regius Professor of Medicine at Oxford; the chairman of the British Organizing Committee is Sir Humphry Rolleston, and the office of the congress is c/o the International Society of Medical Hydrology, 109, Kingsway, W.C.2.

There will be two main subjects for discussion. "Wet and Dry Climates and Weather in the Causation of Disease" will be introduced by Professor G. Danischewsky (U.S.S.R.), Dr. G. Edström (Sweden), Professor de Rudder (Germany), and Dr. E. P. Poulton (Great Britain). The second subject, "Juvenile Rheumatism," will be considered under four aspects, the principal speakers being: *Pathological aspect*: Professor F. Klinge (Germany) and Dr. A. G. Gibson (Great Britain). *Clinical aspect*: Professor L. Findlay (Great Britain) and Dr. H. Grenet (France). *Therapeutic aspect*: Dr. Wilfrid Sheldon (Great Britain) and another opener. *Social aspect*: Dr. F. J. Poynton (Great Britain) and Professor G. Danischewsky (U.S.S.R.). There will be numerous supplementary papers to the discussion on juvenile rheumatism, and it is hoped that supplementary papers will also be received for the first subject.

Visits are to be paid to hospitals in London on March 26, and there will be receptions on the evenings of the 25th and 26th. Arrangements are being completed for the accommodation of congress members in colleges at Oxford; a concert, banquet, and reception have been arranged there; visits will be made to Leamington Spa during the meeting and to Droitwich at the end.

The congress is open to medical men and scientists who are not members of either body on payment of a congress fee. All inquiries should be addressed to the General Secretary, International Congress on Rheumatism and Hydrology, 109, Kingsway, London, W.C.2.

The Bath Meeting

The Bath Congress on Chronic Rheumatism is to be held to commemorate the bicentenary of the Bath Royal National Hospital for Rheumatic Diseases on March 31, April 1, 2, and 3. It will follow directly after the International Congress at Oxford. The meeting will be opened by Lord Horder on the evening of Thursday, March 31, and his address will be followed by a mayoral reception and dance. The next day will be devoted to a discussion on "Gout and Rheumatism of Metabolic Origin," and papers will be read by Sir Walter Langdon-Brown, Professor Weil, and Drs. Hill, Gibson and Kersley, Weissenbach, and Francon, the discussion being resumed by Drs. Geronne, van Breeman, Kahlmeter, and Freund. There will be a banquet in the evening. On Saturday, April 2, papers will be read by Professor Pemberton, Professor Hench, and Professor Davidson. The following morning a demonstration of cases will be given at the hospital.

The meeting will be open to all practitioners, and further particulars may be obtained from the honorary secretary, c/o the Bath Royal National Hospital for Rheumatic Diseases.

The Middlesex County Council on December 21 adopted proposals for a large increase of hospital accommodation in the county, and for the provision of seaside convalescent homes near Southampton and at Mundesley, Norfolk. The sum of £658,000 will be spent on extending the West Middlesex County Hospital, Isleworth, and £650,000 on extending the Hillingdon County Hospital, Uxbridge.

healthy and diseased, but he was not aware that *B. typhosus* had ever been found in swine. His understanding was that for practical purposes man was the only animal which could carry typhoid bacilli for any period.

The Question of Carriers

Sir Walter Monckton next took the witness to the question of carriers.

If a carrier had been working in the well, what would you say to that as the cause of the outbreak?—In my opinion that is the most probable cause of this outbreak, but I cannot consider it at all as conclusive. It is a question of probabilities, as is usually the case in typhoid outbreaks. In my opinion the most probable cause in this case is the existence of a carrier.

Are carriers usually regarded as of two kinds, those in whom the infection is conveyed by the faeces and those in whom it is conveyed by the urine?—Yes.

Is a person necessarily a carrier continuously?—He may be intermittently a carrier.

By Sir Humphry Rolleston:

Is there any way from a bacteriological point of view of distinguishing between the faecal and the urinary carrier? Does the one more constantly than the other give a positive result?—Generally speaking, the faecal type are less intermittent than the urinary.

When you mentioned two types of carriers, I suppose you regarded a third form—namely, a person with a suppurating abscess in connexion with bone disease—as too rare to merit attention?—That is a possibility, I appreciate that.

When would you think that an established carrier can be acquitted of having an evil result—after three or a larger number of negative examinations for the bacillus?—I should say a larger number than three, but I should hesitate to give a number.

What would you say as to the time interval between examinations—consecutive days or consecutive weeks?—I would suggest that if five or six examinations were carried out at intervals of five or six days and were uniformly negative, that is about as much as one should reasonably be expected to do, though I should not regard the result as conclusive in view of the medical history. In the case of a urinary carrier I should want more tests and over a longer period.

In further reply to Sir Walter Monckton, the witness said that the Addington well could undoubtedly be made a safe source of supply. Chlorination was one of the most important processes from the point of view of bacteriological purification. By adding coagulant a much wider purification was obtained. Sir Humphry Rolleston asked whether there was evidence that the coagulant had any specific action on typhoid organisms. The witness replied that there was no such evidence, but that he imagined that the accumulation of saprophytes on a filter would tend to shorten the life of typhoid bacilli.

Potential Causes of Pollution

Mr. Sylvester Gates, appearing for the South Croydon Typhoid Committee, said that it had been established that the workman who was a carrier was not a urinary case, and he asked Dr. Suckling how he would consider that the infection of the well could be attributed to this man. Dr. Suckling replied that he did not accept the conclusion that because a certain number of examinations had been made and had proved negative, this carrier might not have excreted typhoid bacilli in the urine. There was evidence in literature that certainly more than half of the carriers of the faecal type intermittently excreted typhoid bacilli in that way.

Mr. Gates said that the presence of *B. coli* in large numbers in the well could not be due to a carrier, and suggested massive pollution of some kind, probably from sewage. Dr. Suckling replied that the use of the word "massive" was hardly correct. The *B. coli* test was an extremely delicate one, and if the organisms were found in 1 to 10 c.cm. of water it might indicate that the amount of sewage pollution in that water was of the order of one

part in millions. Mr. Gates further argued that inasmuch as after an attack of typhoid the victim was immunized for the rest of his life, if afterwards he took in typhoid bacilli through the mouth he might become a carrier: therefore, if the carrier in this case had previously suffered from typhoid and had drunk any of the water in this well while working there, it would account for him becoming a carrier, though he would have had nothing to do with the causation of the outbreak. Dr. Suckling replied that in his view the man was a chronic carrier, and had been so for many years, though he admitted there was no proof of this.

Dr. Suckling was also questioned as to the possible reason why only one case had occurred at the mental hospital, which was supplied directly from the source. He said that he thought this might be explained by the fact that while the water was supplied to consumers generally at night, after the men had left off working, it was supplied to the mental hospital mainly during the day, the storage tank there probably being full before the night supply was forthcoming. Further, the hospital had a softening plant, which, although it did not ordinarily effect purification, might, by reason of the fine suspended matter clogging the interstices, act to some extent as a filter.

Sampling of the Water

Asked how often samples should be taken, Dr. Suckling said that no definite statement could be made as to frequency of sampling; it depended on many factors. Regularity was not the main consideration. The sampling should be arranged so as to give analytical and bacteriological information as to the supply, and therefore it was important to take samples at certain times rather than at others. He was questioned about the general character of the analyses (which were not his own) of the Croydon water previous to the outbreak, and passages from his own textbook were quoted to him by counsel with the object of showing that in various respects—as, for example, the absence of any attempt to define the type of coliform bacillus found—they fell below standard, and it was also suggested that the samples were taken by an unskilled person and the reports were not interpreted by an experienced bacteriologist. Dr. Suckling agreed that greater attention had been paid to the chemical analysis, whereas from the health point of view the bacteriological side was the more important. He was not prepared, however, to mention the count for coli which he would allow without anxiety; one could not take one factor in isolation from others, and one never considered a sample water on one item alone.

Mr. Gates drew his attention to the last analysis made on October 29, before the outbreak, when it was reported: "Colonies per c.cm., 230; *B. coli communis* present in 10 c.cm." to which the remark was attached, "This is a good water, but I think chlorination should be used as a precaution." Could a worse water be imagined? It was this water which was at that very time poisoning the inhabitants of Croydon. Dr. Suckling replied that he could not agree with the description of it as a good water. If he had received that sample he would have reported that it was polluted water and must not be put into supply until chlorinated.

Forthcoming Witnesses

Sir Walter Monckton said that the case for Croydon Corporation would be completed after he had called the town clerk and had recalled the medical officer of health.

Mr. Montague Lyons, for the South Croydon Typhoid Committee, said that he proposed to bring forward as a witness a typhoid patient, who could not be out of hospital for ten days. It might be necessary for the cross-examination to take place in hospital in the presence of the members of the tribunal. The evidence would be an extension and confirmation of what had already been discussed.

CROYDON TYPHOID INQUIRY

MEDICAL OFFICER OF HEALTH'S FURTHER EVIDENCE

Dr. O. M. Holden, medical officer of health for Croydon, had been in the witness chair for three days when the report in the last issue (p. 30) was concluded, and his examination continued for two further days.

In answer to Mr. A. H. Forbes, appearing for the Croydon Division of the B.M.A. and the Local Medical and Panel Committee, Dr. Holden said that his Public Health Committee at an early stage decided to give no information regarding the area of the water supply affected. The policy of the committee was to refrain from such publicity as would alarm the public, though there was no specific instruction to maintain secrecy with regard to water or any other subject. There were no medical men or women on the committee. The tackling of the outbreak was his job as medical officer of health, and as soon as he saw the outbreak was not declining he appealed to the best authority he knew—namely, the Ministry of Health. He did not think it would have helped him at all to have called together the local members of the profession. In reply to a question from his own counsel (Mr. Sandilands) Dr. Holden said that not all the medical men in Croydon were members of the British Medical Association; there was in fact no organization representing all of them. Mr. Forbes said that the membership of the Croydon Division was 250, but this included members outside the borough. Dr. Holden agreed with his counsel that he would have been very unpopular if he had notified the local medical men that he was holding a kindergarten class in typhoid for members of the profession who did not feel themselves competent to deal with such cases.

Water-borne Typhoid

The chairman of the tribunal (Mr. H. L. Murphy, K.C.) asked Dr. Holden whether on an outbreak of typhoid, as distinct from isolated cases, investigation did not ultimately lead back to water. Dr. Holden replied that this was not so in every instance, though he agreed that in his own experience of outbreaks in this country since the war water had been the direct cause of most of them. In the early stage of the recent outbreak he could not consider water alone as apart from a number of factors. Mr. Murphy said that perhaps an earlier answer given by Dr. Holden had not quite done him justice; he had said that he could not suspect water until other factors had been eliminated.

At a later stage Dr. Holden mentioned a number of outbreaks due to articles of food where there was apparently no direct communication with the public water supply, notably at Coventry in 1933 and Penzance and Camberwell in 1923.

In reply to Sir Humphry Rolleston, Dr. Holden agreed that the medical officer of health was a specialist in preventive medicine and public health, and should always be glad to receive information and to advise his colleagues in the medical profession who were not so completely immersed as he in the subject which he professed. He regarded the Ministry not as his master but as his superior adviser in cases of need.

Engineering Evidence

Mr. C. E. Boast, Croydon borough engineer, next gave evidence. He said that in April, 1936, chlorination was carried out once or twice a week at the Addington well, and heavier dosages were given in January and May, 1937, owing to certain occurrences, in the first instance the death of a workman at the well and in the second discoloration with clay caused by the construction of another well. The workmen were good and reliable. He had excluded any with signs of tuberculosis, but he had not

in his mind the question of a typhoid carrier. He found it very difficult to believe even now that the outbreak was due to one of these men who was a carrier, though he agreed that the dates of his employment fitted in with that theory of causation.

Mr. H. F. B. Jones, formerly chief water engineer at Croydon, gave confirmatory evidence as to the selection of the men and their trustworthy character. He added that during the work on the well samples of the water were taken each evening before it was turned into the public supply, and if these were not satisfactory the water was pumped to waste all night.

Evidence was also given by Mr. F. S. Ellis, foreman in the water engineering department of the corporation, as to the sanitary precautions at the well. When Mr. R. J. Jackson, chief sanitary inspector, gave evidence that last year 4,000 boy scouts were on a camping ground in the vicinity the chairman said that it would require very strong persuasion to induce him or his assessors—who had visited the locality—to hold that the typhoid organism came from that camp into the Addington well.

Several workmen (who, because of the suggestion that one of their number was a carrier, were sworn in private and referred to by numbers) gave evidence as to the rules about sanitation, and said that to their knowledge these had never been broken.

Evidence of Consulting Bacteriologist

On January 4 Dr. Ernest Victor Suckling, consulting analyst and bacteriologist, was examined. In reply to Sir Walter Monckton he said that he had made a special study of matters relating to water supply, had had a wide experience of chemical and bacteriological examinations of all classes of water, and was well acquainted with waterworks practice. On November 10 he was consulted by the Croydon Corporation; he came to Croydon on the following day, and from that time onwards he had been in daily communication with the officials. All the recommendations he had made had been followed as quickly as circumstances would permit.

Is the supply at this moment, in your opinion, safe and wholesome water?—I am confidently of that opinion. It has been since the date I came here.

You have taken a great number of samples of the water, and I suppose in your investigation on the gathering ground you have acquired a mass of information upon which you have founded your opinion. Have you been able to trace at all the *B. typhosus*?—No, in no case have we succeeded in isolating it.

Is that a frequent difficulty when you are trying to deal with the causes of an outbreak?—That is commonly the case. It is extraordinarily difficult to isolate *B. typhosus* from water, sewage, and the like, but the fact that one gets negative findings does not entitle one to say it was not there.

The trouble is, I understand, that the bacillus is short-lived, and also that it occurs in association with more robust forms of bacteria which result in shortening even that short period. In other words, you start to search for a short-lived bacillus at much too late a period to be likely to find it.—Unless, of course, the source is continuing. Where there is an intermittent admission of typhoid bacilli one is weeks late in starting.

Can it be said that the infection in this case was probably water-borne?—Yes.

You have heard described possible sources of pollution to be found in the gathering ground. Can one exclude the possibility of the infection being brought from the gathering ground into the well?—I do not think that can be definitely excluded, but I regard it as improbable.

What do you say about the short length of latrine trench as a potential source?—I should regard that as the most probable source of typhoid, and that for two reasons: first, its proximity, and, secondly, the fact that it is concerned with human excreta, whereas the other potential sources are largely animal. *B. typhosus* is to be found in human excreta, but not in animal.

In reply to Sir Humphry Rolleston, Dr. Suckling said that certain *Salmonellas* might be found in swine, but

Local News

SCOTLAND

Payment of Hospital Staffs

At a meeting of the Royal Hospital for Sick Children, Glasgow, on December 22, 1937, Sir George A. Mitchell, deputy chairman of the board, made a statement concerning the decision of the directors to pay the members of the medical staff of the hospital. He said that the practice of paying medical and surgical staffs had been started by the rate-aided hospitals, and a demand had now been made that voluntary hospitals should follow suit. The directors of the Royal Hospital for Sick Children were satisfied that the time had come when they must ask the public to support them in recognizing financially in a reasonable manner the great services rendered to them by members of the medical profession on the staff. Times had changed, and many members of the profession, particularly the younger men, found it difficult to make ends meet, and if the medical, and very specially the surgical, services of skilled men were not adequately remunerated they would soon cease to be available. The directors were satisfied that their decision to remunerate the physicians, surgeons, and specialists would commend itself as reasonable and fair to the general public. The cost would be considerable, but they felt assured that the people of Glasgow and the West of Scotland would support them in this movement and readily provide the requisite funds. The Earl of Home, who presided at the meeting, gave some figures of the work of the hospital. In 1883, the first year of the old hospital, there were 260 patients; during 1937, 7,000 children had received treatment in the hospital and 1,076 in its country branch. Out-patients had numbered 92,000, and the daily average number of children resident in the hospital had been 254 and 79 in the country branch.

Institutional Maternity Services in Edinburgh

At a meeting in November last of the Edinburgh Obstetrical Society the president, Dr. Douglas Miller, took for the subject of his valedictory address the history of the Edinburgh Royal Maternity and Simpson Memorial Hospital. Dr. Miller said that in a Minute of the Edinburgh Royal Infirmary of October, 1755, Dr. Thomas Young, who might be regarded as the founder of the obstetrical school in Edinburgh, was given permission to furnish a ward of six beds at his own expense and to use it for the care of lying-in women and for the clinical instruction of students and midwives. This was probably the earliest record of the institutional care of lying-in women in Scotland. In 1791 the Edinburgh Lying-in Hospital, which could accommodate about twenty patients, was founded, largely through the personal exertions and private financial support of Dr. Alexander Hamilton, who succeeded Dr. Young in the chair of obstetrics in 1780. This remained the Edinburgh Maternity Hospital until 1839, when, on the death of Dr. James Hamilton, who had succeeded his father in 1900, the hospital premises were sold. During the next forty years the hospital occupied various sites, and it was not until 1879 that, helped by a generous donation from the National Fund established to perpetuate the memory of Sir James Young Simpson, the present hospital was built and dedicated to the memory of the great physician whose name it bears. The present century had seen a remarkable expansion in all aspects of the hospital's work and the development of many fresh activities. Dr. Miller mentioned particularly the endowment in 1901 of a bed to be reserved for the treatment of diseases of pregnancy, one of the earliest provisions, he said, for ante-natal treatment to

be made in any maternity hospital. The ante-natal department of the hospital was created by J. W. Ballantyne, whose insistent and eloquent advocacy of the claims of expectant motherhood led to the establishment and rapid growth of ante-natal services throughout the world. Another activity of the hospital outside its routine work which called for special mention was the Home for Unmarried Mothers, Lauriston Park. In 1934 the home, which hitherto had been maintained by public subscription, was generously endowed as a memorial to Dr. Haig Ferguson. That the hospital had justified the public's confidence was made clear by the progressive fall in maternal mortality from the extreme of thirty-five deaths per 1,000 for the decade 1880-90 to eleven per 1,000 for 1936, and that despite an ever-increasing number of "emergency" as distinct from "booked" cases. As early as 1909 the directors intimated that they proposed to make an appeal for funds for building and equipping a new hospital which could adequately meet all modern requirements. It was not until 1926, however, that the managers of the Edinburgh Royal Infirmary submitted a proposal to the directors of the maternity hospital for the construction of a new hospital on the site of George Watson's College, and agreed that it should have associated with it in perpetuity the name "Simpson Memorial."

ENGLAND AND WALES

London's New Midwifery Service

On the first day of this year the new domiciliary midwifery nursing service for London came into operation. This new service, which is being provided by the London County Council under the Midwives Act, 1936, is designed to cover the whole of London, and therefore every London mother, irrespective of her financial circumstances, will now be able to call on the services of a fully qualified midwife to act either as a midwife or, if a private doctor is engaged, as a maternity nurse. The full fees proposed to be charged for the attendance of midwives are: £2 for a first confinement, £1 10s. for a subsequent confinement, £1 10s. for maternity nursing. Reduced fees will, however, be charged where the patient or liable relatives are unable to pay the full fees, and where the circumstances justify such action the whole of the fee may be remitted. Over 160 midwives will be employed under the scheme—forty-seven of whom will be employed directly by the L.C.C. and the remainder by arrangement with upwards of forty voluntary organizations. Co-operation with the existing maternity services of the Metropolitan borough councils forms an important part of the scheme, and the midwives will be encouraged to make the fullest use, for the benefit of their patients, of the various services provided by the maternity and child welfare committees of the borough councils. Leaflets giving the names and addresses of the midwives and also the names of the hospitals and district nursing associations with which the L.C.C. has an arrangement can be obtained by applying at the local town hall or public health department, any borough council maternity and child welfare centre, the County Hall, Westminster Bridge, S.E.1, or any of the L.C.C. hospitals.

Queen's Institute of District Nursing

A report on midwifery cases attended by Queen's nurses and village nurse-midwives and another on the nursing of notifiable and other diseases for which public health authorities have power to pay have been issued by the Queen's Institute of District Nursing; they relate to the year 1936. There was an increase of 2,814 in the number of midwifery cases attended in which no medical practitioner was engaged for the confinement, the total being 67,452. Of the 3,897 midwives concerned, 1,166 were Queen's nurses and 2,731 were village and other nurse-

Mr. Sandilands, for the medical officer of health, said that he had had other offers of witnesses in support of the medical officer from all over England, but he proposed only to call one very senior medical officer of health to give evidence as to a medical officer's responsibility.

The Chairman: Is not that statutory?

Mr. Sandilands: I do not think it is altogether.

The Chairman asked Mr. Lyons whether he was in a position to bring forward any positive evidence about contamination by *B. typhosus* from any particular source.

Mr. Lyons: In this case, no, Sir. I can only give you theories and inferences.

The Chairman: There is no reason why you should do more. Your case may well be that there were a number of possible sources. That is sufficient for you. I only wanted to know before I made some observations that I was not prejudging any positive evidence you might later bring forward.

Number of Cases and Deaths

Sir Walter Monckton announced at the sitting of the tribunal on January 4 that the number of cases was 290 and the deaths 35. The names of ten patients dangerously ill with typhoid at Mayday Hospital were posted outside the town hall.

NEW YEAR HONOURS, 1938

In the list of New Year Honours, issued as a special supplement to the *London Gazette*, the names of the following members of the medical profession are included:

G.C.M.G.

The Right Hon. EARLE CHRISTMAS GRAFTON PAGE, P.C., M.B., Ch.M. Minister of Commerce and Deputy Prime Minister of Australia since 1934.

G.C.V.O.

THOMAS JEEVES, Baron HORDER OF ASHFORD, K.C.V.O., M.D., F.R.C.P. Physician-in-Ordinary to the King; Consulting Physician to St. Bartholomew's Hospital.

K.C.I.E.

ERNEST ALEXANDER WALKER, C.B., M.B., Ch.B., F.R.C.S.Ed., Major-General, I.M.S. Lately Director of Medical Services in India, Army Headquarters.

D.B.E. (Civil)

FLORENCE BARRACLOUGH BARRIE LAMBERT, C.B.E., M.B., B.S., D.P.H., J.P. For political and public services in London.

Knighthood

ROBERT JAMES JOHNSTONE, M.B., B.Ch., F.R.C.S., F.C.O.G. Emeritus Professor of Gynaecology in Queen's University, Belfast; Representative of Queen's University, Belfast, on the General Medical Council; Member of the Northern Ireland Parliament; President of the British Medical Association. For services to public health in Northern Ireland.

JOSEPH WILLIAM LEECH, M.D., D.Ch., M.S., F.R.C.S.Ed., J.P., M.P. Member of Parliament for Newcastle-upon-Tyne West Division since 1931; Lord Mayor of Newcastle-upon-Tyne, 1932-3; Sheriff, 1930-1. For political and public services.

WILLIAM GEORGE SAVAGE, M.D., D.P.H. Late County Medical Officer of Health for Somerset; Past President of the Society of Medical Officers of Health.

CHARLES MCMORAN WILSON, M.C., M.D., F.R.C.P., Dean of St. Mary's Hospital Medical School; Honorary Secretary, Faculty of Medicine, University of London.

CHARLES NORMAN PAUL, M.B., Ch.M. Honorary Dermatologist to Sydney Hospital. For public and philanthropic services in the Commonwealth of Australia.

C.B. (Military)

WILLIAM PORTER MACARTHUR, D.S.O., O.B.E., M.D., D.Sc., F.R.C.P.Lond., F.R.C.P.I., D.P.H., D.T.M. and H. Major-

General, A.M.S. Honorary Physician to the King; Commandant and Director of Studies, Royal Army Medical College, Millbank, London, S.W.

C.M.G.

THEODORE GRANT GRAY, M.B., Ch.B., M.P.C. Director-General, Mental Hospitals Department, Dominion of New Zealand.

JOHN NEWMAN MORRIS, M.B., B.S., F.R.A.C.S. For public and social welfare services in the State of Victoria.

PHILIP HENRY MANSON-BAHR, D.S.O., M.D., F.R.C.P., D.T.M. and H. Consulting Physician to the Colonial Office and Crown Agents for the Colonies since 1929; Lecturer and Deputy Director-General, Clinical Division, London School of Hygiene and Tropical Medicine.

ALBERT RUTHERFORD PATERSON, M.B., Ch.B., D.P.H., D.T.M. and H., Colonial Medical Service. Director of Medical Services, Kenya Colony.

C.I.E.

PERCY STRICKLAND MILLS, M.B., B.S., D.T.M. and H. Colonel, I.M.S. Surgeon-General with the Government of Bengal.

FREDERIC ALLAN BARKER, O.B.E., M.D. Lieut.-Colonel, I.M.S. Inspector-General of Prisons, Punjab.

REGINALD VICTOR MARTIN, M.R.C.S., L.R.C.P., D.O.M.S. Lieut.-Colonel, I.M.S. Officiating Inspector-General of Prisons, Bombay Presidency.

GERALD TYLER BURKE, M.D., F.R.C.P. Lieut.-Colonel, I.M.S. (retired). Lately Secretary, Medical Council of India; lately Professor of Medicine in the University of Lucknow.

C.B.E. (Military)

BRYAN PICKERING PICK, O.B.E., M.R.C.S., L.R.C.P. Surgeon Rear-Admiral, R.N. Honorary Surgeon to the King.

O.B.E. (Civil)

JANET VERA GOOD, M.R.C.S., L.R.C.P. Senior Woman Medical Officer, General Post Office.

EDWARD POHAU ELLISON, M.B., Ch.B. Chief Medical Officer and Deputy Resident Commissioner, Cook Islands, Dominion of New Zealand.

JOHN CHARLES FULTON, M.B., B.S. Medical Superintendent, Launceston Public Hospital, State of Tasmania.

The Rev. PETER MCGREGOR SHEPHERD, M.B., Ch.B. Representative of the United Free Church of Scotland Mission in the Bechuanaland Protectorate.

HUGH MORLEY OLIFF LESTER, M.R.C.S., L.R.C.P., D.T.M. and H. Colonial Medical Service. Deputy Director, Sleeping Sickness Service, Nigeria.

M.B.E. (Civil)

SELINA FITZHERBERT FOX, M.D., B.S. Founder and Director of the Bermondsey Medical Mission.

AINSLIE CLIFFORD WILLIAM DESSA, Indian Medical Department. X-Ray Department, Irwin Hospital, Delhi.

WILLIAM STANISLAUS MARTIN, Indian Medical Department. Civil Surgeon, Coonoor, Madras.

RAI BAHADUR PITAMBER PANT, Civil Surgeon, Etawah, United Provinces.

JOHN MAXWELL HALL, M.R.C.S., L.R.C.P. Colonial Medical Service, Senior Sanitary Medical Officer, Jamaica.

PAULINE VERSFELD MURRAY, M.B., Ch.B. For medical services in the Nyasaland Protectorate.

Kaisar-i-Hind Medal (First Class)

SARAH ANDERSON JAMIESON RANKINE, M.B., Ch.B. Medical Officer, St. Margaret's Hospital for Women and Children, Poona City, Bombay. For public services in India.

Mrs. MARY HILDA YOULE REMFRY, M.B., B.S. Wife of Mr. Justice C. O. Remfry, Bengal. For public services in India.

JOHN MICHAEL PEREIRA, M.B.E. Major, Indian Medical Department (retired). Superintendent, Patna Medical College Hospital, Bihar. For public services in India.

HARI VISHWANATH TILAK, M.B., B.S., F.R.C.S.Ed. Medical practitioner, Bombay. For public services in India.

heart disease, had an embolism in the third part of the axillary artery, which was successfully removed. The second case had an embolism at the bifurcation of the brachial artery. Embolectomy was successfully performed with recovery of the limb; the patient, however, died three weeks later from cardiac failure. Section of the sutured artery showed normal healing in the wall and the presence of a satisfactory lumen. In the third case, with sudden disappearance of the radial and ulnar pulses, a clot was removed from the bifurcation of the brachial artery, but this case was unsuccessful, and later gangrenous changes became manifest in the other limbs. Brachial plexus block anaesthesia was used in all three cases.

Correspondence

The Science of the Health Resorts

SIR,—With reference to Dr. Alfred Cox's letter in the *Journal* of December 18, 1937 (p. 1249), may I say that a scheme of teaching was framed to meet the varying needs of students, practitioners, and specialists, and was adopted by the International Society of Medical Hydrology at its annual meeting in Austria in 1936. It has now been submitted by the society's representatives to Governments and universities in the constituent countries. Facilities for teaching are understood to include provision for necessary research. The society's scheme is as follows:

1. That elementary instruction in medical hydrology and climatology be given to medical students as a part of general therapeutics, and that opportunities be provided for visits to the spas, with practical demonstrations.
2. That postgraduate study be made available for physicians and general practitioners to enable them to choose the right cases for spa treatment and the right spa for the case, and that study tours to the spas ("voyages d'études médicales") be organized for this purpose.
3. That at one or more of the central universities in each country advanced instruction ("cours de perfectionnement"), both theoretical and practical, be made available for those wishing to specialize in one of the branches of hydrological practice.
4. That the teaching of medical hydrology be held to include the following subjects: (a) The properties of medicinal waters and their uses internally and externally (crenotherapy); the accessory physical methods which are used at spas and other health resorts, such as sun and air baths, manipulations, and exercises; and climatology. (b) The medicinal uses of water (hydrotherapy) in hospitals, municipal baths, and town clinics, sanatoria, etc. (c) The properties and uses of marine baths and climates (thalassotherapy) with accessory physical methods of treatment.

The society's proposals have evoked considerable interest. As Dr. Cox reminds us, in some countries university teaching of this character already exists, as in France. In others, where there are few or no spas, the study of climates on the coast or in the mountains is of major importance, especially in relation to delicate children from the towns. In England the University of London did a great work by bringing within the reach of students from all parts facilities for study and special qualification in many subjects that had no place in the ordinary curriculum. It was not the fault of the University of London that a lectureship in medical hydrology and climatology was not founded more than twenty years ago or twelve years ago. Such opportunities do not return.

At present the word "physical" is in the ascendant. It is proposed to push this sharply defined "science of the health resort" into the new physical omnibus. That word

of many meanings is just now fully occupied with education, training, "jerks," and apparatus. Fortunately for another, better inspired, member of the physical family, radiology, it has missed the omnibus and is making good progress under its own colours.

But, Sir, there is a more serious side to this question. They say that in Germany half the people are now following "natural" ways of healing. *Absit omen!* But it may well be asked: Are the remedial powers of Nature no concern of the medical scientist? Should it not be one of the objectives of modern medicine to discover and restore our lost contacts with the energies in Nature? Persistence in a policy of separatism must mean increasing impoverishment to the medical body of any country. Perhaps it may be allowed to me to plead for unity in medicine, for inclusion rather than exclusion, not because it is expedient but because to my mind it is the only true ideal of our profession and is able to bring enrichment to its science and dignity to its practice.—I am, etc.,

London, Dec. 25, 1937.

R. FORTESCUE FOX.

Applying for Hospital Posts

SIR,—Perhaps you will allow one who has had nearly forty years' experience as applicant or elector to say something in defence of the personal interview.

In the first place I entirely agree with some of your correspondents that the official testimonial is an anachronism and should be abolished. It has degenerated to a mere form, which is in most cases disregarded by the electing body. Secondly, where the field is a large one the "short list" should always be employed and ample notice given to the selected candidates: not less, certainly, than a week. But to ask any body of electors to elect from the "short list" without a personal interview, other than the official appearance before the election committee, is, I venture to think, a mistake. Any man who is going to work either with a fellow member of the staff or with a house officer may reasonably desire to see and talk with his prospective colleague before he is asked to give a vote. Therefore I think that for the limited numbers of the "short list" the personal interview must be retained.

The applicant, even if his candidature should be unsuccessful, must not suppose that the time devoted to the interview has necessarily been wasted. It has more than once been my fortune to be able to help an unsuccessful candidate on a later occasion owing to the favourable opinion I have formed at our interview.

Lastly, I venture to hope that the statements of one of your correspondents on the character of his reception represent a most exceptional experience. All members of a hospital staff have themselves at some time been applicants, and must surely have a genuine sympathy with their applicant callers, and a desire to make the interview a pleasant memory to both sides.—I am, etc.,

Basingstoke, Jan. 1.

HUGH THURSFIELD.

Gastro-enteritis due to *B. dysenteriae* Sonne

SIR,—In view of the frequent mention of gastro-enteritis recently, I trust that the following case report will be of interest.

The illness appeared to begin in the evening of December 21 at a time when the patient, aged 26, was in his usual good health, with symptoms he described as being like a cold in the head with slight general bodily discomfort. He went to the office the next day (December 22), and was sent home in the afternoon on account of feeling weak and feverish, having had no lunch that day. In the evening he com-

midwives, a decrease of 89. Of the patients attended, 17,734 (26.3 per cent.) were primiparae. The number of maternal deaths was 174, corresponding to a mortality rate of 2.58 per 1,000 births and 2.65 per 1,000 live births. This compares rather more favourably with the figures for the two previous years; the rates attributable to sepsis being respectively 0.93 per 1,000 total births, 0.97 in 1935, and 1.25 in 1934. Seventeen patients died from non-puerperal causes, which reduced the maternal mortality from puerperal causes in 1936 to 2.33 per 1,000; the rate in urban areas was 1.58 per 1,000 and in rural areas 2.89. Of the total cases, 61,910 were in England, with a maternal mortality figure of 2.94 per 1,000, and 5,542 in Wales, with a mortality rate of 2.16. The number of times medical aid was requisitioned for mothers was 23,565 (36.7 per cent.), and for infants 4,119 (6.4 per cent.). The number of forceps cases was 4,287. As regards the causes of maternal death, 36.2 per cent. were sepsis (37.5 in 1935); and accidents of labour were 31.6 per cent. (28.6 in 1935); the eclampsia percentage was 11.5. Seventy of the fatal cases were not delivered by the midwife because it was necessary to summon medical aid before birth. Various difficulties were encountered due to failure of the patients to take advice, and it appeared that forty of the patients who died should have been booked with a doctor: five women refused adequate ante-natal care. The number of cases in which a medical practitioner was engaged and the midwife acted as maternity nurse was 32,504, representing an increase of 1,586 on the number for 1935. A considerable amount of home nursing was undertaken by Queen's nurses for notifiable cases. There was a slight increase in the number of pneumonia cases attended, and it was notable that there was only a difference of 7.1 per cent. in the recovery rate of those nursed in urban areas where hospital accommodation was easily available and in rural districts where the removal of the patient was much more difficult in cases of acute illness. Epidemics of measles in various parts of the country resulted in a large increase in the number of cases dealt with by Queen's nurses, but the proportion of children who afterwards developed pneumonia was smaller than usual. The large number of children under the age of 5 who suffered from non-notifiable diseases was very obvious, and it is concluded that this fact indicates that the medical profession, the local authorities, and parents are realizing more and more the necessity for trained nursing care, even in those conditions which might seem to be of less importance than the acute illnesses generally associated with infectious diseases. The total number of visits paid in respect of the nursing of cases of notifiable and other diseases for which public health authorities have the power to pay was no fewer than 1,027,152 in respect of 69,686 cases. Of these 14,479 were cases of pneumonia, while tuberculosis, uncomplicated influenza, and measles each accounted for over 4,000 cases.

The Heberden Society

A quarterly meeting of the recently formed Heberden Society will be held at the house of the Medical Society of London, 11, Chandos Street, W.1, at 8.30 p.m., on Thursday, January 13, when Dr. William Goldie of the University of Leeds will read a paper, illustrated by lantern slides, on "The *Streptococcus haemolyticus* in the Aetiology of Rheumatic Fever and Rheumatoid Arthritis." Dr. Mervyn Gordon, F.R.S., and others will take part in the discussion. All medical practitioners are cordially invited to attend. The society is composed of clinicians who are or have been working at the British Red Cross Clinic, Peto Place, N.W. Its object is the study of the rheumatic diseases, mainly from their clinical aspect. A limited number of medical practitioners who have not worked at the clinic but who are interested in the study of arthritis and allied conditions are eligible for election. Further particulars may be had from the honorary secretary, Dr. Kenneth Stone, 58, Chesterfield House, W.1.

Medical Society of London

The second half of the 165th session of the Medical Society of London opens on January 10 with a pathological meeting at 8 p.m. Discussions will be held at 11, Chandos Street, W.1, at 8.30 p.m., as follows: January 24, recent advances in surgery of the sympathetic nervous system; February 14, what can be expected of deep x-ray therapy; February 28, causes and treatment of flatulence; March 14, uraemia; March 28, diagnosis and treatment of lung abscess. The Lettsomian Lectures, on "A Survey of the Changes and Results of Treatment of Diabetes in the Last Fifteen Years," will be delivered by Dr. George Graham on February 21 and March 2 and 7, at 9 p.m. The annual general meeting will be held on May 9, at 8 p.m., and will be followed by the Annual Oration, on "Planning a Hospital," by Sir Henry Gauvain, and a conversazione.

Reports of Societies

FEMORAL EMBOLLECTOMY

At the December meeting of the Liverpool Medical Institution, with the vice-president, Dr. R. E. ROBERTS, in the chair, Mr. E. N. WARDLE read a paper on femoral embolectomy.

Mr. Wardle traced the history of embolectomy from Suabanejeu's first attempt at the operation in 1895, and pointed out that most of the early operations had been upon the femoral artery; the first successful case recorded was that of Labey in 1911. Information collected during the war period upon the suture and ligation of injured blood vessels was of great importance, and the paper of Professor Key of Stockholm, in 1923, was the first authoritative review of a series of such cases; he had collected fifty-one from the literature, including twelve of his own. Geoffrey Jefferson of Manchester (*British Medical Journal* 1925, 2, 985) later published a paper with a record of the cases observed since Professor Key's account had appeared. The condition usually occurred in patients with heart disease, but several cases had been observed in which this aetiological factor could not be found. The symptoms and physical signs of the lodgment of an embolus at the division of the common femoral artery were briefly described, together with the steps of the operation for its removal. It was emphasized that the success of the operation depended very largely upon the diagnosis being made and the embolus removed within two hours of its lodgment.

A patient was then demonstrated upon whom Mr. Wardle had carried out this operation in November, 1936. The points of aetiological interest were that the embolus occurred in the left femoral artery nine days after an operation for an injury to the right ankle; and that at no time did the patient show any evidence of a cardiac lesion. Four days after embolectomy he had pain in the chest, but no definite signs of a pulmonary embolus were ever found. He was shown to have now a comparatively normal circulation in the leg, without any swelling, even after being on the limb all day. The points put forward for discussion were: the source of the embolus, whether the femoral artery was now patent at the affected area; and whether it would have been just as effective to tie the vessel above and below the site of lodgment of the embolus and its associated thrombus.

General Discussion

In the discussion which followed Mr. F. ROBERTS EDWARDS described three personal cases in which the embolus was removed. The first case, a patient with

logical point of view. Though he naturally requires to know the chief facts in the history and clinical condition of the patient, he is not expected to make a complete clinical examination, or to assess the relative value of the evidence obtained from various sources, or to advise the patient what treatment is required. It is the fact that the radiologist is less likely to be swayed by other considerations and concentrates on the x-ray evidence that makes his opinion so valuable to the surgeon. If the two opinions on the films agree the patient is in all probability having a correct interpretation placed on this evidence. If the two disagree a consultation between the two types of specialist, always desirable, becomes imperative. Should the patient wish to get other opinions in this or any other country, is he not entitled to any and all of the films that have been taken?

I am well aware that the above description of the duties of a radiologist will not meet with the approval of some of our radiological colleagues, but they do express, I believe, the views of surgeons as a whole. Not for a moment is it suggested that as a matter of experience there is any difficulty put in the way of films being seen by any and every medical man whom a patient may wish to consult—far from it; but this is done in many cases purely as a matter of courtesy. Abdominal and chest cases, I imagine, call for special consideration, since the taking and interpretation of films form but a part of the x-ray examination. I have purposely confined myself to a class of case of which I have had experience.—I am, etc.,

London, W.1, Jan. 3.

H. A. T. FAIRBANK.

Treatment of Burns

SIR,—Mr. P. H. Mitchiner's statement in his excellent article on the treatment of burns and scalds in the *Journal* of January 1 (p. 27), that gentian violet does not produce coagulation, must have caused considerable surprise to all who have had opportunities of using this method.

It is true that this dye was not introduced for its coagulant properties but primarily as an antiseptic; it was found, however, that in addition to any antiseptic properties it possessed it also formed a tough, firm eschar similar in many ways to that produced by tannic acid but also having certain advantages over the latter. Briefly, these advantages are: (1) The eschar is flexible, and in spite of the increased movement allowed there is less liability for cracking to occur over the flexures. (2) It does not contract as much as does the eschar formed by tannic acid, and hence in those cases in which a burn completely encircles a limb there is less liability to swelling and oedema. (3) The presence of underlying sepsis can be diagnosed more easily and suitable treatment instituted earlier. (4) Gentian violet is said to be less destructive to isolated islands of epithelium.

These are some of the advantages of gentian violet considered as a coagulant, but in addition it is an antiseptic, which tannic acid is not. A further point worth mentioning is that an aqueous solution can be preserved indefinitely, but even with the addition of antiseptics tannic acid rapidly deteriorates. The chief disadvantage that I have found lies in the fact that gentian violet is a dye, and not only the patient but everything that comes in contact with him acquires a purple colour which is very difficult to remove.—I am, etc.,

London, W.2, Jan. 3.

Surgical Registrar, St. Mary's
Hospital.

Treatment of Psychoneuroses

SIR,—The pronouncements of Dr. T. A. Ross (*Journal*, December 18, 1937, p. 1247) on the subject of psychotherapy cannot fail to be of peculiar interest, for most of us are familiar with Dr. Ross's work, *An Introduction to Analytical Psychotherapy*. With Dr. Ross's main thesis—namely, that a large proportion of psychoneurotic patients are readily amenable to treatment of a comparatively brief duration—I am in cordial agreement. Indeed, I am strongly of the opinion that the difficulties of this form of treatment have been in the past, and are still, grossly exaggerated. To state, as one of your correspondents does, that "the psychological approach is still a tortuous by-way without any guideposts" seems to me, to say the least of it, a considerable overstatement of the case. Surely the stream of psychological literature which has poured forth from the medical presses of this country, of America, and the Continent ever since the war should have helped a little to blaze the trail if not to make a well-worn path. In view of this wealth of literature and the diversity of opinions which it implies it would appear that the practice of psychotherapy is a highly individual matter, and one which, except in its main outlines, cannot in the last resort be taught or communicated to another. Such at least has been my personal experience; and in such modest *exposés* of my methods as I have at times essayed I have been acutely conscious that though the general scheme of approach was communicable the real essence of my treatment somehow eluded explanation. To those psychological purists who deprecate the intrusion of a personal factor on the part of the operator this of course will be sheer heresy. So far, however, from making any apology for such an attitude, I see no reason why one should not enlist the full resources of one's personality in the practice of psychotherapy as in any other form of treatment. Further, I would suggest that those (mainly psycho-analysts) who fondly imagine that they have freed themselves from every trace of what I suppose one must call transference take perhaps an unduly sanguine view of the situation.

To come to less controversial matters, I think that the function of psychotherapeutic clinics is definitely limited. The mere number of cases to be treated renders this necessarily so, and I quite agree with your correspondent Dr. E. Fretson Skinner (December 11, 1937, p. 1196) that the out-patient clinic in its present form provides no solution of the problem, though I think it might be of definite service as a sort of clearing-house. The only kind of clinic of which I have had any experience is the Ministry of Pensions Clinic, instituted for the treatment of war neuroses. Judging by that experience, I should imagine that the type of material which presents itself at such a clinic as the one at Sheffield would be extraordinarily diverse. If, however, the clinic did no more than recognize and segregate the cases of indubitable psychosis and potential psychosis, it would still perform a considerable service. Cases, for instance, of manic-depressive psychosis with suicidal tendencies, euphemistically described under the term "nervous breakdown," might at last be recognized for what they are, and so enabled to live out their legitimate term of years. Essentially, however, the treatment of the psychoneuroses is an individual matter and one which does not fit in readily with the ordinary routine of general practice. Its proper milieu and atmosphere are provided neither in the crowded clinic nor in the busy consulting-room of the ordinary practitioner. For this and other reasons it would seem that the treatment of

plained of generalized severe myalgic pains, headache, and "hot and cold feelings." When seen he was in bed, shivering and with a flushed face, a dry furred tongue, and a dry hot skin; there was no sore throat or cough; the temperature was 104° F., pulse rate 80, and respiration rate 20. General physical examination revealed no other abnormal signs. The condition was thought to be influenza, or possibly malaria as he had been in India, where he had had, amongst other things, malaria, typhoid fever, and dysentery, amoebic and bacillary (Flexner, Shiga). He was given aspirin 10 grains and a hot drink. About midnight he felt very sick, for the first time apparently, and vomited. Later on in the night he vomited several times more and had diarrhoea—three or four liquid stools, brown and yellow in colour, with no blood, pus, or mucus, being passed. A blood film taken at the height of the temperature during the night showed no abnormality of red or white cells, and no protozoa. The urine was normal. The next morning (December 23) a purge was given, and soon produced a large watery stool, after which the patient said he felt much better. The temperature fell rapidly to normal, and after a slight rise that evening remained there. The diarrhoea was easily checked by a mixture containing belladonna, opium, and chalk, and the patient recovered rapidly except for some diarrhoea and griping abdominal pains for the next few days, due to his going on to a very full diet the day he was allowed to get up and go out—for which indiscretion Nature exacted full retribution in the form of a set of painful haemorrhoids.

Bacteriological examination (by Dr. C. W. Morley) of the stools taken on the third day of the illness (December 23) showed a large number (50 per cent.) of non-lactose-fermenting organisms, which after fermentation and agglutination reactions proved to be *B. dysenteriae* Sonne. The patient usually had his meals in various restaurants in the city, and insisted that his food was invariably of the very best. However, the night before his general malaise began (December 21) he dined alone at a strange restaurant, where he had a "made-up" meat steak, regarding the integrity of which he was not so certain.

The interesting features of this case are the unusual onset with a rigor simulating severe influenza or malaria; the comparatively late development of acute gastro-enteric symptoms (that is, late on the second day); and the marked severity of the condition. It is thought that it would be of interest to record that an attack of gastro-enteritis of this nature could be associated with a definite *B. dysenteriae* Sonne infection, which is usually presumed to produce gastro-enteric disturbances of mild degree.—I am, etc.,

THOMAS G. OSLER.

St. Mary's Hospital, London,
W.2, Jan. 1.

* An article on Sonne dysentery, by Dr. Reginald Miller, appears at page 64 of this issue, and an annotation on the subject was published in the *Journal* of December 11, 1937, at p. 1176.—Ed., *B.M.J.*

Use and Abuse of Antiseptics

SIR,—The two articles by Professor L. P. Garrod and Mr. Geoffrey Keynes on the use and abuse of antiseptics must have proved both interesting and instructive to a large number of medical practitioners.

Some months ago my complacency over hypodermic injections was rather disturbed by reading of a case of gas gangrene occurring after a varicose vein injection, and a case of severe cellulitis following an ordinary subcutaneous injection of, I think, morphine. It occurred to me that chloroform should be a good solution to keep both syringes and needles in, and I am now doing this. It is only necessary to pass them through spirit before using. This readily dissolves any of the drug remaining. I

understand that chloroform is not only lethal to all forms of micro-organisms, but also to their spores, and perhaps one of your contributors could confirm or refute this.—I am, etc.,

Bristol, Dec. 29, 1937.

CHARLES CORFIELD.

Who Owns X-Ray Negatives?

SIR,—In Dr. Asten's letter on the above subject in the *Journal* of January 1 (p. 47) the following statement appears:

"The radiologist, like the biochemist and the bacteriologist, and possibly others in a team, contributes his skill as an aid to diagnosis, and it is the opinion based upon such skill and knowledge alone for which payment is made, and not anything tangible such as a mere photograph."

In your footnote to this letter you quote, without adverse comment, a medico-legal correspondent as having said (when this subject was under discussion four years ago): "The point that the films had no intrinsic value seems sound as expressing the view that the patient pays for service and skill only."

So far as specialists are concerned, at any rate, these statements are surely founded on a misconception of the parts played respectively by the radiologist and the specialist in the investigation and treatment of a case. Take a fracture case, for instance. The surgeon sends the patient to the radiologist so that films may be taken and be available for the surgeon, to assist him in deciding the best method of dealing with the case. A report without the films is useless in most cases, no matter how eminent the radiologist. After setting more films are taken to enable the surgeon to decide whether the position of the fragments is satisfactory or not. Later yet more films are taken, again for the use of the surgeon, who alone has to take the responsibility of saying whether splints may be discarded with safety or not. The radiologist's report in most fracture cases is really superfluous. Now suppose the patient, before the treatment is completed, is obliged to move to a distant part of the country or perhaps go abroad—he expects, and rightly expects in my opinion, to take the films with him so that they may be at the disposal of the second surgeon as they were of the first. Supplying him with prints is not enough. Personally I feel sure that most patients with fractures visit the radiologist with no other idea than that films will be taken for the use of their respective surgeons. When the first set of films are taken at a hospital the position depends on whether or not the patient has paid for the x-ray examination. If he has not the films are the property of the hospital, and it is only by courtesy that they are placed, temporarily, at the disposal of an outside surgeon. If, on the other hand, fees have been paid at the hospital, the films should be at the disposal of the patient to take to any surgeon he may select. For many years I have acted on this view in talking to patients, and, almost without exception, they have had no difficulty in obtaining possession of the films. When we turn to other conditions affecting bones and joints the position is not quite the same, since the radiologist's opinion is now of definite value, though the patient often does not realize this. In all such cases the patient expects the surgeon to examine the films and give his opinion on them. It is the surgeon who has to correlate the evidence the films provide with that gleaned from clinical and other sources, for he alone has to take the responsibility of advising the patient. The radiologist gives his opinion on the films essentially from the radio-

Dr. Gray seems to hint that other persons in that list besides himself feel aggrieved. Out of 113 nominators concerned only one withdrew his name after the publication of Mr. Mitchiner's address. The feeling of the graduates to whom the circular was sent may be gauged by the fact that within a few days of the circulation of the address, and several weeks before polling day, considerably more than one-third of the whole accessible electorate had signified in writing their intention to vote for Mr. Mitchiner and their desire to add their names to any list of his supporters. There can be no question that the policy announced by the association and by Mr. Mitchiner commands the overwhelming support of the electorate. Perhaps it was knowledge of this fact which deterred Dr. Gray and his friends from bringing forward a candidate in support of their views and in opposition to Mr. Mitchiner.

Dr. Gray accuses the Graduates' Association of being unconcerned with the interests of education and of the students of London University. The primary purpose of the association since its foundation nearly forty years ago has been to defend the interests of graduates. That it has done so is clear from the response the graduates have made from time to time, especially during the last fifteen years that I have been president, in support of candidates nominated by the association in University elections for Parliament, for the Senate, and for the Standing Committee of Convocation. But it is surely rash of Dr. Gray, who apparently is in favour of a change that would degrade the final University examination in medicine to the level of the Conjoint diploma, to reproach the association, which desires to maintain that examination at its present high degree-level, with indifference to the interests of education and of students of the University who are destined to become graduates and who are vitally concerned to maintain the status of their degree.

I submit, Sir, that on the more important question, the "problem of the final M.B., B.S.Lond." as you have described it, Dr. Gray is unacquainted with, and consequently misrepresents, the facts. The University Grants Committee transferred to the Court of the University as long ago as 1929 the office of Mentor of the Schools, together with the function of distributing grants to those schools. Dr. Gray is mistaken both as to the source of the complaint and the terms in which it was made. The latest pronouncement of which I am aware on this question was made by the Court to the Senate in December, 1936, in the following statement:

"In making their grants to schools, the Court's attention was again directed to the small number of students in medical schools who take a university degree, and the Court resolved that, in communicating to the medical schools the Court's decisions with regard to grant, those schools be informed that the Court have noted with regret that in comparison with the rest of the country the number of London students who achieve a university degree is very low; that they are aware that the causes contributing to this are many and complex; that the recent changes in the scheme of the examinations of the University may have the effect of making a degree more easily accessible; and that the Court hope that at the end of the next quinquennium the figures will show an improvement."

The final paragraph, in its suggestion that the recently revised medical curriculum would have the effect of making the degree "more easily accessible," and that the improvement could not very well be manifest "until the end of the next quinquennium," contradicts, in my submission, Dr. Gray's suggestion that pressure is being exercised on the University by any grant-giving body. The very temperate and sober statement by the Court,

especially in its last sentences, gives point to the letter from my colleague Professor Greenwood in your issue of January 1. It is the Board of the Faculty which in completely ignoring that very important and laborious revision is, in fact, flouting the advice of the Court.

The real explanation for the relatively "small number of students in London medical schools who take a university degree" is to be found, as the Haldane Commission quite explicitly stated, in the circumstance that the Conjoint Board of the Royal Colleges offers to London medical students a qualification to practise of lower standard, exacting a shorter period of training and rendered more accessible by, among other factors, the greater frequency with which the Conjoint Final Examination is held as compared with the M.B., B.S. (four times a year as against twice a year). This competition of a lower qualifying examination with the M.B., B.S. has become less serious in the last few years; stirred by a growing consciousness of their responsibility to the university from which they derive so large a proportion of their income, the London medical schools are increasingly restricting their admission of students to those entering for a university course, either of Oxford, Cambridge, or London, and this rule is likely to become universal. Whereas at the date of the Haldane Report less than one-third of the students at London medical schools were undergraduates of London University, at the present time the proportion of such undergraduates varies from 93 per cent. to 49 per cent., the average for the twelve schools being over 70 per cent.

The position is thus immensely better than it was when the Haldane Commission reported. Moreover, in that report it is stated that "the average annual entry of University of London students in the London medical schools for the quinquennial period ending 1909 was 80," including women students, who constituted a very considerable proportion. The last issue of the *University Calendar* shows that in the twelve medical schools there are now no fewer than 2,890 students entered for the London degree, a figure which indicates that the average annual entry for the quinquennium ending with 1937 was approximately 500—six times as large as in 1909.

Professor Greenwood very pertinently points out that the Colleges as corporations are licensing, not teaching bodies, and "can make little contribution to the solution of an educational problem." In this connexion it is important to note that the Commissioners who framed the present Statutes for the University, following the Haldane Commission, deliberately eliminated the representation of the Royal Colleges upon the Senate previously enjoyed by them, and by so doing clearly indicated their conviction that a complete educational separation between the Colleges and the University was desirable. With Mr. Mitchiner's election to the Senate there will be eight medical members of that body; they are likely to be evenly divided upon this question of co-operation of the University with the Colleges, and no clear medical lead can result. Dr. Gray seems to suggest that there is no harm in bringing forward this proposal for co-operation because the other members of the Senate can be relied upon to defeat the proposal if its defeat is desirable. That seems to me a curious encouragement for its presentation, and as he himself says the objections to it are many and various and may well prove "insuperable," I find it increasingly difficult to understand what motive can explain the persistence with which Dr. Gray and his friends are pushing it.—I am, etc.,

London, W.1, Jan. 3.

E. GRAHAM-LITTLE.

the psychoneuroses is likely to remain the province of those who devote themselves solely or partially to this speciality.

I think that the profession as a whole is fully alive to the extent to which a neurotic element enters into many disorders where it would not *a priori* be suspected. So far from underrating this possibility, there seems to me a great danger of exaggerating the part it plays. In an age when such terms as "inferiority complex," "escape from reality," "fantasy formation," and the like are on everybody's lips there seems little likelihood of overlooking the psychological aspect of things.—I am, etc.,

Leeds, Dec. 27, 1937.

J. E. MIDDLEMISS.

Hormone Treatment of Prostatic Hypertrophy

SIR,—While acting as ship's surgeon on a voyage to Buenos Aires I came across a passenger who was doing the round trip for the benefit of his health.

He had been advised to undergo an operation for enlarged prostate, but owing to bronchial trouble a sea voyage had been ordered before the operation. Having recently read in a French journal of some successful results from hormone therapy, I suggested giving him a course of treatment if I could procure a preparation of testosterone salts in Buenos Aires. I succeeded in obtaining the testosterone propionate in sesame oil. Before starting treatment I verified the fact that he was suffering from a hypertrophied prostate with incomplete chronic retention. At first I limited the injections to two a week; after the sixth injection the nocturnal frequency of micturition was reduced from six or seven times to once, and the dysuria had decreased. The pain and heaviness over the bladder region also disappeared. I then gave him three injections a week. After the twelfth injection, in addition to the functional improvement there was also a decrease in the size of the prostate, and his physical and mental condition showed a marked improvement. I administered six more daily injections until there was an indication of overstimulation. I think I might say that on arriving in London the patient was very grateful.

The conclusion may be drawn that hormone therapy, at least in uncomplicated cases of prostatic adenoma, is satisfactory and free from ill effects.—I am, etc.,

Woodford Green, Dec. 28, 1937.

Causation of Rickets

SIR,—In your annotation on perspectives in biochemistry (*Journal*, December 25, 1937, p. 1285), which, however, does not profess to be a comprehensive one, there is no reference to the article by Sir Edward Mellanby in which he reiterates his belief in the existence of the so-called "cereal-factor" or "toxamin" as a potent agent in the causation of rickets. It is possible to disagree with his views for the following reasons.

The time taken by the human infant to double its birth weight is 180 days, that for the puppy-dog nine days. Corresponding with this, the milk of the human species contains 1.6 per cent. protein and 0.035 per cent. calcium, while the figures for that of the bitch are 7.1 per cent. and 0.241 per cent. Sherman suggests that for the child of 3 years and upwards an allowance of 1.0 gramme of calcium, in the form of a quart of cow's milk, should be given each day. Considering the rapid growth of the young dog and the likelihood that a puppy, a few days old, of one of the moderate-sized breeds could easily drink in a day 100 c.cm. of bitch's milk, containing 0.241 gramme

of calcium, an allowance of 1.0 gramme of calcium a day for the puppy of from 6 to 7 weeks and over would not seem to be excessive. In Sir Edward Mellanby's 1925 paper (M.R.C. Special Reports, No. 93), however, we find that the amount of calcium supplied each day to puppies of 6 to 7 weeks and over was of the order 0.045 to 0.085 gramme. In harmony with this and due essentially to the existent calcium deficiency, as I have previously pointed out, the condition exhibited in the rib sections illustrating this report is one of atrophy and osteoporosis only, without, so far as I can observe, there being any evidence of the presence of rickets.

On these grounds, as well as on others which space will not allow me to discuss here, I have serious doubts as to the reality of the existence of the "cereal-factor" or "toxamin," and as to the part that it is alleged to play in the production of rickets. These remarks, which apply equally to the case cited above in which osteomalacia was produced in adult dogs on somewhat similar diets, are based on an article of mine which was published in the *British Medical Journal* (1933, 2, 599), and on one by Emslie and myself in the *Biochemical Journal* (1934, 28, 1503).—I am, etc.,

Aberdeen, Dec. 12, 1937.

J. P. MCGOWAN.

The Problem of the Final M.B., B.S.Lond.

SIR,—After reading Dr. A. M. H. Gray's letter (*Journal*, December 25, 1937, p. 1300) I wish in thanking my nominators to assure them that I intended no discourtesy to anyone, and certainly not to Dr. Gray, to whose comradeship and military teaching I am so greatly indebted.

I had thought my views on this subject were realized, as I have never been at pains, when it has been mentioned in my presence, to conceal that while in no way averse to reciprocation between all the bodies whose students enjoy the facilities of the London medical schools, I should view with dismay any proposal for co-operation between only two or three of them as being unlikely to be to their advantage, or to enhance the prestige and popularity of their degrees. I have therefore viewed with increasing anxiety the proposals for such a partial agreement, and so find myself, in this matter, at one with the Graduates' Association.—I am, etc.,

PHILIP H. MITCHNER.

London, W.1, Jan. 1.

SIR,—In your issue of December 25, 1937, Dr. A. M. H. Gray makes an attack upon the University of London Graduates' Association, for the actions of which as President I take full responsibility, and I would ask you therefore to allow me to answer him.

Shortly after Mr. Mitchiner's adoption as the association's candidate he handed to the clerical staff of the association a batch of nominations (including Dr. Gray's) for publication with his election address. In conversation with Dr. Gray some considerable time after the issue of the association's circular he told me that while dissenting from Mr. Mitchiner's views, with which he had been long familiar, on the particular issue of co-operation with the Royal Colleges, he warmly desired his election on personal grounds. He made no protest to me regarding the inclusion of his own name in the list of nominators, and his letter in the *British Medical Journal* was the first intimation that I received of his objection to what he must know is the usual procedure in University elections, in which nominations of candidates are published and are invited for no other purpose.

state it. It is to make shoes that will accommodate the toes in their normal alignment, with room for them to move within the shoe. To achieve this, the inner border of the shoe must be quite straight, because the big toe lies, normally, in the line of progression. Such a shoe is known as a "sandal-form" shoe. No walking shoe of this shape is displayed by any of the big shoe firms because it is not fashionable; and considerations of fashion are far more powerful than those of comfort or health. Correct shoes need not be expensive; they wear well and keep their shape since they have not to withstand abnormal pressures as with "fashionable" shoes.—I am, etc.,

London, W.I, Dec. 29, 1937.

ALFRED C. JORDAN.

SIR,—In connexion with Dr. Thomas Marlin's letter on this subject (*Journal*, December 11, p. 1198) I should like to give the results of seventeen years' experience with marching boots for soldiers.

There are racial differences in the length and width of feet. A fair proportion of young soldiers start their army careers with toes already retracted or deformed by civilian boots or shoes. Permanently cramped, retracted, deformed, or ankylosed (including hammer) toes are more common than many people would care to admit. In order to conform to civilian "fashion" army boots are generally too tight over the toes for comfort. I have had experience of three types: (1) British boots, (2) French boots, both of which are rather narrow over the toes for the normal foot, and (3) American boots, which are wide over the toes but are too heavy. A soldier, therefore, has to choose either a pair of boots which fit at the heel and cramp the toes, or else a pair which fit easily and give room for the toes but are loose at the heel. The result is that after marching, say, ten miles he will probably have blisters on the toes in the first case, or on the heels in the second.

The boots should always fit at the heel and should be wide enough to enable the toes to expand to their natural limit when marching, as they would do if the feet were naked. In most cases compression of the toes reduces the circulation, and after a long march oedema may be seen above the ankle, or sloughing of portions of the skin between the toes, or there may be cheesy deposits. This interference with the circulation can also be the cause of varicose veins of the leg. I have even seen a case of osteomyelitis occur after a march of several weeks from septic abrasions over one or more of the small bones of the foot.

Some time ago I went to a surgical bootmaker and got him to make me a pair of "experimental boots" fitting close at the heel and being extra wide over the toes. As a result there was complete circulation and ventilation in the boots by the unimpeded movement of the toes. After long marches my feet were warm and comfortable and the socks were dry, and I was one of the very few who were not dog-tired, since pain and discomfort cause fatigue. The bootmaker measured my instep and made the uppers accordingly. I have a high instep, and the uppers did not meet for lacing. He had evidently been making boots for "flat-footed" people, in which case the instep is supported by the sole. By introducing two fingers under the tape during the second measurement this shortness in the width of the uppers was rectified.

New marching boots should be steeped in a pail of water for forty-eight hours when the tannin and other chemicals used in "curing" produce a dark-brown colour in the water; they can then be dried and "dubbed."

The type of shoes seen in bootmakers' windows for children of tender years, which are somewhat spatulate over the toes, do not look ungainly, and if the style in boots and shoes for grown-up people could be changed to this pattern a new generation would grow up with normal feet.—I am, etc.,

London, W.I, Dec. 17, 1937.

G. G. COOPER.

Partial Glossectomy as a Cure of Stuttering

SIR,—I read with interest Dr. William Brockbank's account (*Journal*, December 18, p. 1239) of the operation advocated in 1841 for the cure of stammering. There is no logical reason why it should not correct the stammering habit, but the adoption of such a course indicates complete ignorance of speech training. The hangman can cure indigestion, but there are other and better methods!

The two main factors in speech and song are the production of the vocal tone in the larynx and the moulding of that tone into words during its passage through the mouth by movements of the tongue, lips, and jaws. Perfect speech and perfect song depend upon maintaining a correct balance between these factors, which may be said to be conflicting, inasmuch as the continuity of the vocal tone is necessarily broken for the pronunciation of the explosive consonants, which are the particular bugbear of the average stammerer. In a less degree the vocal tone is checked for all the other consonants. In contrast, we are all familiar with the singer who is concentrating on vocal tone and neglecting his word formation. The same organs are used in speech and song, but in speech the tendency is to concentrate on the words and to neglect the voice, while in song the opposite is found. In nearly every case the stammerer can sing fluently, because if he concentrates on vocal tone rather than on word formation he corrects the loss of balance. His tongue, lips, and jaws have been too active in comparison with his larynx; since the tongue is the chief agent in consonant production, it is easy to believe that if the mobility of the tongue is curtailed surgically it will help to re-establish the correct balance. Anyone who has had a dyspeptic ulcer of the tongue will remember the efforts subconsciously made to modify the tongue movements in speech. It is obvious, however, that since the same organs are used in speech and song the stammerer who can sing must need very little readjustment to enable him to speak.

It must be remembered that the stammerer can very often mimic dialect and accent, the reason being that he is then compelled to pay more attention to the vowel sounds, for which the vocal tone is resisted in a less degree than in the case of the consonants. This again substantiates the theory that stammering is a habit of unbalanced speech, and that the obvious method of correction is to establish correct balance.—I am, etc.,

London, Dec. 22, 1937.

H. ST. JOHN RUMSEY, M.A.,
Speech Therapist and Lecturer at
Guy's Hospital.

Morsier and Junet (*Schweiz. med. Wschr.*, Oct. 16, 1937) describe two cases of myoclonus of the pharynx and larynx. In both the movements were rhythmical, symmetrical, longitudinal, and regular, occurring from forty to two hundred times a minute. The movements are due to simple muscular contractions. They are not influenced by respiration, and it is not known whether they occur during sleep, but they sometimes stop during voluntary movements—for example, deglutition. They are produced most commonly as a result of arteriosclerosis or of inflammatory lesions.

Opportunities for Women in Medicine

SIR.—"Cambridge Woman Graduate's" letter in the *Journal* of December 25, 1937, raises a vexed question. In its wider implications, however, apart from Cambridge graduates in medicine, the grievance is not a new one. To put it plainly, women, as a rule, are tolerated, not welcomed, in the medical profession, or, with a few outstanding exceptions, in its lower ranks only. To take the Public Health Service, in which I happen to have been in the past most interested, there are few, if any, of the higher appointments, such as medical officer of health in the counties or county boroughs, held by a woman. There are, indeed, assistantships in plenty, but it is depressing to work for years with no prospect of promotion, it may be, subordinate to one who is only superior by virtue of his sex; and these remarks apply, *pari passu*, to other branches of the profession, such as honorary posts in hospitals, which naturally go to alumni of these hospitals, most of which are closed to women undergraduates.

I may add that being off the active list, having started my medical career in the 'nineties, I have no axe to grind, but I cannot but feel that even now, when many more posts are open to them than was the case in the past, women are still *cæteris paribus* at great disadvantage in competition with men in the medical profession. I could enlarge at further length on the subject if your space permitted.—I am, etc.,

EVA MCCALL.

Sussex, December 25, 1937.

SIR.—I was delighted to read in the *Journal* of December 4 (p. 1124) of the opportunities for medical education afforded to women students at the new West London Medical School, and agree with the writer of that article and with several of your correspondents that such facilities are long overdue. But there is still cause for anxiety. The injustice of the present position—"that women are deterred from entering the profession"—is made clear by the article, and the unfairness of past events hinted at—"the experiment . . . was tried . . . and abandoned . . ."—though just how unfair those happenings were can only be known to those who, like myself, were actually working at a hospital while an anti-women campaign was being conducted. In view of all this, it is disquieting to learn that "there is no present intention of confining the school to women students" and that "the future development of the school in this respect cannot be foreseen," though if there are lessons to be learnt from history in this case they might be foreseen only too clearly. In plain language, is there any guarantee that these twenty-five places, or any proportion of them, will be reserved for women students, not only now but in the future? Unless this is assured, can we expect the women to believe that they are not being made use of in an emergency, only once more to find the doors shut against them when their usefulness has passed?—I am, etc.,

DOUGLAS E. BARTON, M.B., B.S.

Morden, Surrey, Dec. 28, 1937.

Correct Footwear

SIR.—One item of women's clothing stands out prominently as responsible for discomfort and disability. It is the shoe, and in particular the toe of the shoe. Take the shoes of a small child and of a woman. Compare the shapes of the toes, and it will be seen that in the latter there is insufficient toe-room. Look at the plantar aspect

of the toes of the average small child and compare it with that of the average woman. In the former the toes are separate and straight, in the latter there is evidence of lateral compression-cramping and some degree of deviation from the straight. The inner border of the shoe should be straight up to the level of the tip of the great toe. If it deviates outward it will in time produce some degree of valgus deformity. Where this deviation is great, as in the shoe with the comparatively sharp mesial point, gross deformity will result in the course of time. Long years of wearing anatomically incorrect shoes will in many cases spoil the feet and rob them of beauty. It may be years before symptoms send the patient to seek advice, and by that time deformity is established and restoration of form and function well-nigh impossible.

Fashion decrees for women's feet a shape of shoe-toe which is anatomically incorrect, and which is the chief factor in altering the shape of the toes. Where this alteration is great it is accompanied by other changes in the feet which, but for the offending shoe, need never have occurred. To preach to the unwilling in private practice the doctrine of the straight inner border is unprofitable and a mere beating of the air. To attempt to lessen the amount of disability due to preventable foot troubles it is desirable that the manufacturers should put on the market a model acceptable to women and at the same time anatomically correct. Education as to correct footwear and the ills which follow the use of the incorrect shoe, in the course of years, bear fruit and stimulate a demand which is at present all too small. The Ministry of Health should have figures and be able to assess the amount of trouble arising from "bad" shoes, and will be able, too, to judge if it would be worth while to arrange for annual "foot" lectures by expert lecturers to the senior classes in girls' elementary schools and secondary schools throughout the country. I plead for room for the toes. May the importance of toes and shoes receive due notice in the national fitness campaign! Here is a field for preventive medicine, and at low cost. Once correct shoes have achieved popularity they should cost no more than to-day's shoes. There remains only the cost of the essential education. Results would not come quickly, but by 1980 figures should be starting to show a drop in the number of chiropodists and in the number of operations for hallux valgus!—I am, etc.,

C. GIBSON.

Worthing, Dec. 30, 1937.

SIR.—In the *Journal* of December 11 (p. 1198) Dr. Thomas Marlin tells us that many disabilities may be traced to foot-discomfort; he is certain the whole construction of footwear requires alteration. Dr. Tom Hare (December 25, p. 1302) insists that the medical profession should direct the correct shoeing of mankind. It is safe to say that over 90 per cent. of women in this country and in all classes of society show obvious deformity of the feet. The commonest deformity is a crowding together of the tips of the toes; instead of lying side by side and separate, as in bare-footed tribes, the little toe is deflected inward, the great toe outward, while the intermediate toes to which prevailing shoe-fashions allow no space assume the well-known "hammer" form. Constant pressure upon abnormal projections thus arising leads to corns, bunions, and other painful local reactions that give constant employment to an army of chiropodists. Especially common is a large and hideous projection at the metatarso-phalangeal joint of the great toe. The same, though to a lesser degree, is true of many other feet. To remedy these troubles is difficult, but prevention is simple, so simple that it seems ridiculous to have

We have received from Bristol the following note supplementing the obituary of Professor GEORGE BUCKMASTER, which appeared last week at page 48: Buckmaster published a number of papers on blood pigments and their derivatives, and spent considerable time on the blood gases, for which work he and J. A. Gardner devised their tapless blood-gas pump—an instrument designed to avoid experimental errors through leakage. He was specially interested in the carriage of CO₂ in the blood, and pointed out the possibility of this gas combining with haemoglobin. He also studied chloroform anaesthesia and the blood gases during anaesthesia. In 1919 he was appointed Professor of Physiology in the University of Bristol, a post he held with great distinction for ten years. Buckmaster was essentially a student and a philosopher, with no time or interest for utilitarian affairs. A great and compelling teacher and a much-loved colleague, he became a very part of the life of Bristol University. He was a brilliant and witty conversationalist, and it seemed a cruel irony of fate that his last illness left him for months completely aphasic. He married Miss Amy Elizabeth Brooks, and had one son and one daughter. His son died as a victim of the war in 1919. His daughter, after taking her medical degrees, married Dr. Ronald Tasker.

We regret to announce the death on December 14, 1937, after an illness of only two days, of Dr. GEORGE BURROWS BROWN, aged 58. He was educated first at Rossendale Grammar School, and afterwards at Durham University, where he graduated at the early age of 21 years as M.B., B.S. Then he proceeded to the West Indies, where he practised for four years. On his return to England he practised in Manchester. On the outbreak of the great war he joined the R.A.M.C., and served as a temporary captain on all fronts; on the termination of the war he retired with the honorary rank of Captain R.A.M.C. He was medical officer of health for Failsworth for ten years, when he retired to Worthing. After some years' rest on account of ill-health he decided when his health was regained to start practice in Worthing, and was appointed district medical officer. Dr. George Brown was much loved by the poor, to whom he was ever kind and generous. He leaves a son and two daughters; the younger daughter, Mary, is a student in her fourth year at Sheffield University. His brother, Dr. J. Percival Brown, practises at Bacup.

Dr. JOSEPH HAROLD ASHWORTH, D.P.H., died on December 18, 1937, after a long illness, at his residence in Kersal, Manchester, aged 67. Educated at Manchester Grammar School and Owens College, he graduated M.B., Ch.B.Vict. in 1894. As a student he represented the then Owens College at lacrosse, and was on two occasions a member of the side which was beaten in the final of the Senior Flags competition. After a short period of residence at the old Clinical hospital he left to take over the practice founded in Cheetham Hill by his elder brother, the late Percy Ashworth, M.D., F.R.C.S. He remained in practice without interruption till 1916, when he volunteered and was accepted for foreign service in the R.A.M.C. He went to France as lieutenant attached to the 57th General Hospital in 1916, but was invalided home with myocardial deficiency in 1917. His heart and general health never fully recovered, and he was obliged to give up the strain of a busy general practice in 1920, since which date he lived in semi-retirement in Kersal. Dr. Ashworth married in 1901 Bertha, youngest daughter of the late P. J. Ramsay, J.P.; she died in 1927. He is survived by a daughter and two sons, the elder of whom, Dr. H. K. Ashworth, is visiting anaesthetist to the Royal Infirmary and other Manchester hospitals.

We regret to announce the death on December 23, 1937, at Hungerford, Berks, of Dr. THOMAS GORDON STARKEY-SMITH. He was born in 1880 the youngest son of T. Starkey-Smith, F.R.C.S., of Warrington, Lancs. and studied medicine at St. Thomas's Hospital, taking the English Conjoint diplomas in 1907, the M.B., B.S.Lond.

in 1908, and the M.D. in 1910. After holding the post of senior obstetric house-physician at St. Thomas's Dr. Starkey-Smith began general practice, and during the war was medical officer in charge of the Savernake Red Cross Hospital. His appointments included those of anaesthetist to the Savernake Hospital, medical officer and public vaccinator for Hungerford, and medical officer to the infirmary and the infant welfare centre. He was well known locally as a Freemason and cricketer, and through his enthusiasm for ancient customs gave strong support to the picturesque Hocktide celebrations at Hungerford. He joined the British Medical Association in 1912 as a member of the Reading Division.

Mr. DONALD DOUGLAS DAY, who died at Harleston, Norfolk, on December 20, 1937, aged 79, was formerly well known as a surgeon in Norwich and the surrounding country. At St. Bartholomew's Hospital he won a senior scholarship and the Lawrence scholarship in 1880, in which year he qualified M.R.C.S., L.S.A., and graduated M.B., B.S.Lond., with a gold medal in surgery. After holding a prosectorship at the Royal College of Surgeons of England he became house-surgeon to the Norfolk and Norwich Hospital, and making his home in that city was later elected assistant surgeon, and finally full surgeon, to the hospital. He obtained the F.R.C.S. in 1883. Mr. Day was a member of the British Medical Association for half a century, and in his years of active surgical practice contributed notes on lithotomy and on abdominal operations to these columns.

Dr. DAVID MORGAN, for sixteen years medical superintendent of the Cunard Steamship Line, died on December 26, 1937, after a long illness, aged 75. He studied medicine at University College, London, and Edinburgh, graduating M.B., C.M.Ed. in 1884. For some years he helped Hugh Owen Thomas and Sir Robert Jones in their orthopaedic work, and from 1897 to 1910 he was examining officer for the Cunard Company at Liverpool for passengers and emigrants to America. Dr. Morgan was one of the earliest to take up medical radiology, and for some time acted as radiologist to the Royal Southern Hospital, Liverpool. He joined the British Medical Association in 1889, and at the Annual Meeting at Liverpool in 1912 was vice-president of the Section of Electrotherapeutics. Since his retirement from the service of the Cunard Company in 1926 he had lived at Hampstead Way, London, N.W. During the war he superintended the fitting out of the *Mauretania* as a hospital ship and sailed in her to the Dardanelles.

One of Glasgow's oldest medical practitioners, Dr. ROBERT WILSON STUART, died recently after a very brief illness. The son of an Aberdeen merchant, Dr. Stuart went to Glasgow in the early 'seventies, and, after studying at Anderson's College and the Royal Infirmary, took the L.R.C.P. and S.Ed. in 1879. Going to Shetland as an assistant, he succeeded to the practice of his principal at Dunrossness, and shortly afterwards was appointed medical officer of health for the districts of Dunrossness, Sandwick, and Cunningburgh. A few years later he returned to Glasgow, where for close on half a century he has carried on a large and successful practice in the north-west area of the city. Soon after his return he became associated with the late Dr. Angus Macphree in the work of the Glasgow Training Institute for Nurses, in Scotia Street. The institute had been started by Dr. Macphree some years earlier for the purpose of improving the status of handymen and raising them from the "Sairey Gamp" plane to one approaching nearer that of the trained nurse. When the State Registration of Midwives Act came into force during the war handymen who were in active practice at the time were admitted to the new register on passing a very nominal examination. It was Dr. Stuart's boast that practically all the Glasgow "howdies" so admitted had been trained by Dr. Macphree and himself. Dr. Stuart, who had been a member of the British Medical Association for fifty-

Obituary

H. B. BUTLER, F.R.C.S.Ed.

Senior Surgeon, Royal Surrey County Hospital, Guildford

The untimely death of Harold Butler on Christmas Day was a shock to his colleagues and many friends. For over thirty years he had worked for the people of Guildford. His great surgical skill, kindness of heart, and selfless care of his patients, both in and out of hospital, had endeared him to hundreds of people in the district. The crowded cathedral church on the day of his funeral bore witness to their affection.

Harold Branson Butler was born in Guildford on October 13, 1875. After leaving St. Paul's School he went on to Sidney-Sussex College, Cambridge. Wander-

lust lured him to New Zealand for a while, after which he returned to study medicine at St. Bartholomew's Hospital, taking his M.R.C.S., L.R.C.P. in 1901. After a short period in general practice at Buckingham, and later as medical officer at Powick Asylum, he returned to Guildford to assist his father in his practice. Always surgically minded, he took the Fellowship of the Royal College of Surgeons of Edinburgh in 1903, and devoted himself to developing his skill in surgical technique and

diagnosis. By visits to surgical clinics, including Lord Moynihan's at Leeds and that of the Mayo brothers in America, he and his colleague Mr. Eric Sheaf made themselves familiar with the latest surgical methods. They were thus able to raise the standard of provincial surgery at Guildford to a very high level.

For over thirty years Mr. Butler has worked assiduously at the Guildford Hospital, never sparing himself by night or day, always finishing his list, even when fatigue warranted his leaving some work to his deputy. This ultra-conscientiousness surely left its mark on his strong constitution. An attack of double pneumonia two years ago should have warned him to conserve his energies, but his work, especially his hospital work, came first, and he worked just as hard until a few days before Christmas, when his cerebral arteries gave way.

H. B. Butler had been a member of the British Medical Association for thirty years. He was president of the Surrey Branch in 1925-6 and chairman of the Guildford Division in 1927-8. He contributed some valuable papers to the medical journals, notably those on shock and gastrectomy. He was a justice of the peace for Guildford, and rendered valuable service to the town. For his work with Red Cross hospitals during the war he was made an M.B.E. He is survived by his widow, née Hilda Bethune Denham Smith, and his son Denis and daughter Audrey (Mrs. John Parker). His colleagues at the Royal Surrey County Hospital have lost a fine surgeon, a lovable colleague, and an unselfish friend.

T. B. J.

MALCOLM BRICE SMYTH, M.B., B.Ch.

Physician, Belfast Hospital for Sick Children

It is with regret that we record the death, on December 21, 1937, of Dr. Malcolm Brice Smyth, at his residence in University Square, Belfast. It was only a few weeks ago that he was carrying out his ordinary routine, and now an illness of two months' duration has removed one of the best examples of the family doctor, a physician loved and esteemed by his patients and by them regarded as healer and friend.

Malcolm Brice Smyth was a student of Trinity College Dublin, graduating B.A., M.B., B.Ch. in 1900. He acted as house-surgeon in the Royal Victoria Hospital, Belfast, with a view to a career in surgery, but he gave up his interests in surgery to carry on the family practice on the sudden death of his brother, Sidney. Notable as an active sportsman in his youth, he maintained his interest in shooting and fishing until within a few weeks of his death. With his patients he was the personification of kindness, and earned their love and devotion—not from an excess of sentiment, but because of an exceedingly practical mind that saw when the need was greatest and where help could be best applied. His father was co-founder of the Belfast Hospital for Sick Children with the late Sir John Fagan, and all his life Malcolm Smyth maintained a deep and earnest interest in the welfare and progress of this institution, which has steadily established itself as one of Belfast's outstanding charities over a period of sixty-five years. He succeeded his brother, Sidney, who was honorary physician to the hospital, on his death, and for nearly thirty years was a member of the medical staff of this hospital so intimately connected with the name of Brice Smyth. For several years he was on the surgical staff of the Belfast Maternity Hospital. To it he rendered valuable service as one of the best obstetricians in and around Belfast. Some years ago he resigned from the active staff, and had since been an honorary consulting surgeon to the newly developed and reorganized Royal Maternity Hospital. He was a vice-president of the Section of Diseases of Children at the 1937 Annual Meeting of the British Medical Association in Belfast. Sincere sympathy is felt towards his widow and their three daughters.

Mr. Howard Stevenson, F.R.C.S., writes:

The death of Malcolm Brice Smyth leaves a blank not only in the ranks of the medical profession in Belfast but among a large circle of friends. His medical education took place at Trinity College, Dublin, where he had the distinction of being captain of the rugby fifteen. After graduating in 1900, Smyth returned to Belfast, where his father and brother were engaged in practice, and obtained a resident post in the Royal Victoria Hospital. He early displayed a keen interest in diseases of children, and was elected visiting physician to the Belfast Hospital for Sick Children, a position he held until his death. Enjoying a large practice, Smyth belonged to that small group, now unfortunately dying out, the old-fashioned family doctor. His relation with his patients was much closer than that of merely a physician—he was their confidant and friend. His loss in this respect will be much felt. Shooting and fishing were his relaxations; at both he excelled. He was never happier than when out for the early morning flight of duck or casting a fly over a pool. I think we must look to these sporting instincts to account for much of his great popularity among his friends. It was impossible to be in Smyth's company without realizing his charm of manner and tolerant outlook; it was equally impossible to imagine him doing a mean act or speaking an unkindly word.

absorbent in water from the Scout reservoir reaching taps of as much as twenty-eight parts per million. In 1929 a serious complaint of lead poisoning was made. By October, 1930, the Board had full knowledge that cases of lead poisoning had occurred, but did not apply for borrowing powers to erect a hardening plant till May, 1932. A Ministry of Health inquiry was held in May, 1933, but no hardening plant was installed until 1936. An analytical chemist who had tested the water said in evidence that it could not be passed through lead or tin-lined pipes (such as were fitted in the public-house) without absorbing some of the lead. If it stood for an hour it might absorb a dangerous quantity. The question for decision was, therefore, whether a water undertaker who supplies to the stop-cock outside premises water that is pure but capable of absorbing dangerous quantities of lead has a duty to warn the occupiers of that danger. The Commissioner found that the Board had satisfied their statutory duty but that they had also a common law duty to warn the consumer that he must take the necessary precautions to prevent the pure water which they supplied from becoming contaminated with lead. He was satisfied that they had not given the occupiers warning of any kind, and he therefore awarded the couple £873 damages and costs.

Universities and Colleges

UNIVERSITY OF LONDON

The following candidates have been approved at the examination indicated:

M.S.—Branch I (Surgery): G. S. Ferraby, K. L. James, C. J. B. Murray. Branch IV (Laryngology, Otolaryngology, and Rhinology): M. P. Ellis.

UNIVERSITY OF BIRMINGHAM

The following medical degrees were conferred at a congregation held on December 17:

M.D.—H. B. Hunt.
M.B., Ch.B.—J. H. Briscoe-Smith, R. T. R. Freshwater, K. A. Marandi, P. E. Morris, Frances C. Myatt.

UNIVERSITY OF BRISTOL

The following candidates have been approved at the examinations indicated:

FINAL M.B., Ch.B.—Section II: R. L. J. Derham, H. D. T. Gawn, M. E. M. Herford, F. J. W. Hooper, G. L. Page (with distinction in public health), Anna H. Silberstein. In Group II (completing examination): P. N. Heron, P. K. Jenkins.

NATIONAL UNIVERSITY OF IRELAND

UNIVERSITY COLLEGE, CORK

The following candidates have been approved at the examinations indicated:

M.D.—T. O'Neill.
M.B., B.Ch., B.A.O.—J. C. Dundon (first-class honours), J. A. Allen, P. Buckley, P. Coffey, K. A. Flaherty, F. S. Kelleher, D. J. G. Maher-Loughnan, C. Marchant, E. F. Mulcahy, Ellen M. M. Murphy, P. Murphy, J. S. O'Mahony, P. J. Ryan. Part I: Mary Corbett, J. Hutch, L. Kelly, D. J. R. McConnell, D. O'Keefe, P. O'Keefe, Mary F. O'Leary. Part II: C. J. Clohesy, G. R. Cubitt, J. Fitzgerald, J. G. Paton, M. F. Ronayne.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

The course of lectures for 1938 is arranged as follows: January 17, Professor J. Cole Marshall, The surgical treatment of detachment of the retina; January 19, Professor Reginald T. Payne, Cancer of the stomach as a surgical problem; January 21, Professor R. C. Brock, Pathology, diagnosis, and treatment of intrapulmonary new growths; January 24, Professor William E. Underwood, Recent observations on the pathology of hydronephrosis; January 26, Professor J. I. Munro Black, The lympho-epitheliomata; January 28, Professor Maxwell Ellis, The function of the bronchial tubes; January 31, Professor T. W. Mimpriss, Treatment of retention of the testis; February 2, Professor Harold Rodgers, Endoscopic appearances of normal gastric mucosa and its variations in disease; February 4, Professor T. F. Todd, Rectal ulceration following irradiation treatment of carcinoma of the cervix (pseudo-carcinoma of the rectum); February 7, Professor H. J. B. Atkins, Chronic mastitis;

February 9, Professor T. Stewart Heslop, An experimental study of the neurogenic origin of peptic ulceration; February 11, Professor P. B. Ascroft, An experimental study of the surgical treatment of arterial hypertension; February 14, Sir Arthur Keith, F.R.S., The prehistoric people of Mount Carmel; February 16, Dr. W. E. Gye, Some recent work in experimental cancer research. All the lectures begin at 5 p.m.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—F. B. Akeroyd, J. S. Lancaster, J. D. B. Perkins.
MEDICINE.—F. Bastawros, F. C. E. Diamond, D. C. Light.
FORENSIC MEDICINE.—F. Bastawros, F. C. E. Diamond, D. C. Light.

MIDWIFERY.—J. M. Hardy, P. H. Hay-Hedde, R. Lipkin.

The diploma of the Society has been granted to F. Bastawros, F. C. E. Diamond, and D. C. Light.

The Services

DIRECTOR OF R.A.F. MEDICAL SERVICES

Air Commodore A. V. J. Richardson, C.B., O.B.E., has been appointed Director of R.A.F. Medical Services, Air Ministry, as from March 1, in succession to Air Vice-Marshal Sir Alfred W. Iredell, K.B.E., C.B., who retires from the Service on that date.

HONOURS

Lieut.-Colonel R. K. Mallam, R.A.M.C., has been appointed an Officer of the Military Division, and Captain G. E. S. Stewart, I.M.S., a Member of the Military Division, of the Most Excellent Order of the British Empire, for valuable services rendered in the field in connexion with the operations in Waziristan during the period January 17 to September 15, 1937.

DEATHS IN THE SERVICES

Lieut.-Colonel CHARLES JOSEPH MACCARTIE, Bengal Medical Service (ret.), was born on March 30, 1851, the son of Daniel MacCartie of Skibbereen, and graduated B.A. and M.D. in 1873 and M.S. in 1874 at the Queen's University of Ireland. He entered the Indian Medical Service as surgeon on September 30, 1874, became surgeon lieutenant-colonel after twenty years' service, and retired on June 25, 1900. All his service was spent in military employment, and he had a fine record of war service: Afghanistan 1878-80 in the actions at Saifudin and Shahjui, severely wounded near Kandahar, mentioned in dispatches in the *London Gazette* of October 24, 1879, medal; Burma 1891-2, medal with clasp; Chitral 1895, the relief of Chitral, medal with clasp; North-West Frontier campaign of 1898, at Tirah, clasp; Mohmand, Malakand, and Bajaur operations, clasp. He was granted a good service pension on September 10, 1927. He was the author of *A New System of Field Hospitals and Ambulances for Hill Warfare*, 1898. He had been a member of the British Medical Association for thirty years.

Lieut.-Col. ROBERT MCLAUCHLAN DALZIEL, I.M.S. (ret.), died at Muckhart, by Dollar, on December 17, 1937, aged 61. He was born on July 13, 1876, and was educated at Dollar Academy and at Edinburgh University, where he graduated M.B., C.M., in 1899. He entered the Indian Medical Service as lieutenant on January 29, 1901, became lieutenant-colonel on July 29, 1920, and retired on January 29, 1926.

Surgeon Major GEORGE SULLIVAN CLIFFORD HAYES, O.B.E., late 1st Life Guards, died at Le Manoir Forest, Guernsey, after an operation, on December 20, 1937. He was educated at Guy's Hospital, and took the M.R.C.S.Eng., L.R.C.P.Lond. in 1902. After filling the posts of clinical assistant at Charing Cross Hospital and resident medical officer at the Hospital for Women in Soho Square he entered the Army, and soon afterwards was posted to the Household Brigade, from which he retired as surgeon major of the 1st Life Guards, and joined the Reserve of Officers. He raised Lord Derby's Field Ambulance in 1915, and commanded it in France in 1915-16. After the war he went to South Africa, where he compiled a report on *The Physical Conditions and Mental Defects of School Children in Southern Rhodesia*, a report to the British South Africa Company in 1920.

three years, was keenly interested in the new Maternity Services (Scotland) Act and in the fight which is now going on among the profession in Scotland for more adequate remuneration for those taking service under that Act and for the insistence on free choice of doctor and continuity of service to the patient. With a long and wide experience of maternity work behind him he had little patience with much that has been voiced by propagandists. Two years ago Dr. Stuart gave up his panel work. Asked how he was filling in the unwonted leisure time thus left him, his invariable answer was, "I'm doing research work. I'm trying to discover when child-bearing became a pathological, instead of a normal physiological, process."

By the death of DANIEL FREDERICK RAMBAUT, M.D. (writes Dr. J. Loughheed Baskin) a very distinguished colleague has passed away, one who was among the earliest medical men to introduce occupational therapy into mental hospitals. He was the registrar of the Medico-Psychological Association many years before it obtained the Royal prefix, for which the late Dr. J. R. Lord was responsible, and three years ago he became its president. Those who knew him in his early life remember him as a brilliant athlete. At the Royal School, Armagh, he was held in great respect. He was the champion hurdler of Ireland, and once succeeded in beating the English champion. He made a mathematical study of this sporting event, and demonstrated that three strides between the hurdles are necessary. He and the late Alexander Macdonald were international rugger men, the latter being captain of the Irish fifteen. He was also a good cricketer and hockey player. Rather short, strongly built, and handsome, he was a good companion and staunch friend, and though his sympathies were with the mentally afflicted, in ordinary life he did not suffer fools gladly.

As one of his old colleagues (writes Dr. H. Horsman McNabb) I know the death of ALEX. HILL GRIFFITH, M.D. Aberd., F.R.C.S. Ed., consulting ophthalmic surgeon, Royal Infirmary, Manchester, consulting surgeon, Manchester Royal Eye Hospital, which occurred at his residence at Woking on November 24, will be deeply regretted by all his old students, friends, patients, and other colleagues. After graduating M.B., C.M. he came to the Manchester Royal Eye Hospital as house-surgeon in 1879, later becoming a member of the honorary staff, and it was here that his chief work was done. From the first he showed his energy and zeal. He was responsible for the introduction of cylindrical lenses in the correction of astigmatism, and his work in diseases of the choroid and vitreous became universally known. Griffith won the Middlemore Prize in 1897, and was the first president of the North of England Ophthalmological Society, in whose meetings and welfare he took the keenest interest. Jovial and kindly by nature, he put his whole heart into his work, and was greatly respected for his sincerity and ability.

Dr. ABRAHAM HEPWORTH ROBINSON of Bridlington died suddenly on December 26, 1937, aged 77. A student of the University of Edinburgh, he took the M.R.C.S. Eng. in 1888 and graduated M.B., C.M. Ed. in 1893. He had practised at Low Moor, Bradford, for about forty years. He took over from his uncle, Dr. Whitterton, and his son, Dr. H. W. Robinson, now carries on the practice, which has been in the family for more than one hundred years. While at Low Moor Dr. A. H. Robinson was an active political worker; he was appointed to the Bench in 1889 and was the senior Justice of the Peace for Bradford. Since his retirement, about fifteen years ago, he had lived mainly at Bridlington. He had been a member of the British Medical Association for over thirty years.

In the obituary notice of Dr. C. E. Jones-Phillipson, published last week, he was incorrectly stated to have been an old student of St. Bartholomew's Hospital. He was, in fact, a St. Thomas's man: a student there from 1891 to 1896.

Medico-Legal

COMPLAINT OF FAULTY DIAGNOSIS

At Manchester Assizes on December 10 Mr. Commissioner (now Mr. Justice) Henn Collins dismissed a claim made by a former policeman against a medical man, that the doctor had failed to examine him properly or skillfully and to diagnose tuberculosis.

The plaintiff said that in May, 1934, he had joined the Lancashire County Constabulary, passed a medical examination, and went through a strenuous course of training. In September he was transferred to the police barracks at Walkden as a probationer. On November 1 he developed a persistent cough, and in January, 1935, he saw the defendant, who did not examine his chest but gave him some medicine. At the end of February the doctor examined his throat and gave him an application. In March his cough became much worse, but the doctor when examining him did not ask him to strip, but applied a stethoscope outside two pullovers and a vest. In May and June he went for a cruise, and towards the end of June he complained to the doctor that his cough was as bad as ever. He felt very tired, his appetite had gone, and his weight had dropped. In July, when he complained he could not carry on his work, the doctor had said, "Nonsense!" In August he was told to take cod-liver oil, and towards the end of the month, when he was too ill to get up, the doctor still did not diagnose anything wrong with him but recommended that he should be sent to a seaside division. He consulted another doctor, who diagnosed tuberculosis, for which he was discharged from the police.

A sanatorium officer said that the plaintiff was suffering from advanced tuberculosis of both lungs with ulceration, and would not work again. His expectation of life was only a few years.

The defendant said in evidence that he had diagnosed catarrh in April, 1935, after examination with a laryngoscope. Later on, examining the chest with a stethoscope and by other methods, he had found nothing abnormal. The plaintiff never was robust, and had not been getting enough food. He was not particularly happy at the Walkden station. On August 1 he had seen the plaintiff at the station and examined him thoroughly. It had never occurred to him that tuberculosis was present, and it was easy to be wise after the event. On August 26 a senior police surgeon had examined him and found no evidence of any localized disease in his lungs. He was a case of long-standing tuberculosis which had shown no signs for a considerable time and had then flared up.

The learned Commissioner, giving judgment, said that a man faced with such an awful blow was apt to attribute his misfortune to some neglect or other. Once it was conceded that the signs of this type of tuberculosis might not be apparent at all times a medical man who failed to detect them could not be charged with negligence. He was satisfied that the defendant had found sufficient physical signs to account for the cough. He could not believe that the doctor had used a stethoscope outside the patient's underclothing, for if he was being slipshod he would not bother to do anything so entirely useless.

LEAD POISONING FROM WATER

An interesting point of law arose during an action tried at the recent Manchester Assizes.

A married couple who had managed a public-house supplied with water by the Irwell Valley Water Board sued the Board for damages for personal injury due to lead poisoning, and alleged that the Board had not carried out their statutory duty. The evidence showed that the couple had suffered illness in 1934 and 1935, had been forbidden to drink more water from their own taps, and had given up their licensed house in June, 1937. Mr. G. L. Lynskey, K.C., said that the highest figure taken by any authority as a standard was one part of lead in one million parts of water, and that above that proportion the water was dangerous. Between 1928 and the end of 1935 there had, he said, been a

EPIDEMIOLOGICAL NOTES

Typhoid Fever.—At the time of going to press 290 cases have been notified in the Croydon outbreak with thirty-seven deaths. During the week ended January 1, 1938, there were three cases and five deaths.

Diphtheria and Scarlet Fever.—During the week under review notifications of diphtheria were lower both in London and in England and Wales than the "expected" numbers based on the median values for the last nine years, and much lower than those for the corresponding week last year. The same holds true for scarlet fever, with the exception that the figures for England and Wales were somewhat in excess of those for the corresponding week last year—2,244 compared with 2,053. The reduction in incidence of these diseases is particularly opportune in London, where an epidemic of measles is beginning to make itself felt, as it has for several weeks past in Manchester.

Dysentery and Infective Enteritis.—The incidence of dysentery in England and Wales appears to be falling, with 270 cases notified against 411 in the previous week. In Wales there was only one case, against eleven (ten in Swansea) in the previous week. The widespread character of the disease is evident from the mere list of areas chiefly affected (the figures in brackets are notifications in the previous week): Chester, 1 (14); Devon, 28 (42), of which 16 were in Okehampton and 4 in Barnstaple; Essex, 19 (33); Kent, 25 (8), of which 13 were in Tonbridge; Norwich, 29 (21); Nottingham, 7 (21); Stafford, 20 (18), of which 12 were in Cannock; and Surrey, 11 (10), of which 4 were in Carshalton and 2 each in Sutton and Malden. The metropolitan boroughs chiefly affected were: St. Pancras, 12 (14); Lewisham, 8 (21); Islington, 6 (3); and Bermondsey, 4 (7); a few boroughs escaped completely. Of the 17 cases notified in the county of Middlesex 6 were in Hornsey, 4 in Enfield, and 2 in Willesden. The great majority of these cases appear to be of the mild Sonne variety; it is not possible to give the fatality rates as the weekly returns do not include deaths from dysentery. On the other hand, the figures for deaths from enteritis and diarrhoea under 2 years are available but not the numbers of notified cases. The deaths, however, provide a reliable comparative index of the prevalence and severity of these infections. During the week the deaths were 49 and 12 in England and Wales and London respectively, compared with 57 and 15 in the previous week and 44 and 9 in the corresponding week last year.

Medical News

The Hunterian Lecture will be delivered before the Hunterian Society at the Mansion House, E.C., on Monday, January 17, at 9 p.m., by Dr. Gustav Singer of Vienna, on "Functional Disorders of the Intestine."

An exhibition of Chinese art to raise money for Chinese medical relief is being held at 9, Conduit Street, W., and will remain open until January 28.

The German Society of Balneology and Climatology will hold its annual meeting at Kiel from February 24 to 27, when the subjects for discussion among others will be thalassotherapy, including the physics and meteorology of coastal climate, treatment of tuberculosis on the flat land and on the coast, and treatment of children at sea.

In connexion with the jubilee meetings of the Indian Science Congress Association, which opened at Calcutta on January 3 under the presidency of Sir James Jeans, honorary degrees are to be conferred by the University of Calcutta on eight visiting men of science, including Dr. Charles S. Myers, Principal of the National Institute of Industrial Psychology, and Dr. Straub, Professor of Pharmacology at Munich.

The League of Nations has sent a medical mission to the Far East to take measures to prevent or control the spread of epidemics. The mission is headed by Inspector-General Lasnet of the Académie de Médecine. Dr. Hermann Mooser, representing Germany, and Dr. Robert Cecil Robertson, representing Great Britain. The mission will first visit Hong Kong and continue its work in South China.

The first number of a new journal entitled *Konstitution und Klinik* will be published this month under the general editorship of Professor Dr. W. Jaensch and Professor Dr. F. Rott of Berlin, by J. A. Barth, Leipzig. The price is RM. 7.60.

The December issue of the *Journal of Nervous and Mental Diseases* contains a sympathetic appreciation of Dr. Kinnier Wilson by Dr. Foster Kennedy, which was delivered before the American Neurological Association last June.

The issue of *La Presse Médicale* for December 18, 1937, is devoted to articles by Italian physicians and surgeons, including an article by Professor Catterina on the occasion of the fiftieth anniversary of Bassini's operation for hernia.

The Mental After Care Association (founded in 1879) earnestly appeals for funds to carry on and extend its work for early and after-care patients and those suffering from nervous diseases. Nearly 4,000 were assisted last year. The president is Viscount Wakefield, and the secretary Miss E. D. Vickers, 354, Grand Buildings, W.C.2.

Sir Joseph Skevington, consulting surgeon to King Edward VII Hospital, Windsor, since 1903, retired on January 1, but he will remain as honorary radiologist. He was presented with an illuminated album bearing the signatures of the Duke of Gloucester, president of the hospital, and members of the committee.

At the Philadelphia General Hospital a "blood bank" has been established—the second in the United States—where quantities of blood, stored in refrigerated vaults, are immediately available for emergency transfusions.

Mr. Leslie Paton has been elected an honorary member of the Royal Society of Medicine of Budapest on the occasion of the centenary of its foundation.

The University of Paris has recently conferred an honorary doctorate on Professor E. W. Archibald of McGill University, Montreal, who was elected an Honorary Fellow of the Royal College of Surgeons of England in 1927.

Dr. Grégoire, professor of surgery in the Paris Faculty of Medicine, has been elected a member of the Académie de Médecine in succession to the late Professor de Lapersonne.

Dr. Marinesco, professor of neurology at Bucarest, has recently been elected Grand Officer of the Legion of Honour. He is the first Rumanian doctor to receive this high distinction.

A Reuter telegram states that the epidemic of infantile paralysis in Victoria has now reached a figure of 1,400 cases notified, and there have been seventy-eight deaths. The disease is spreading into South Australia and Tasmania.

A medical centre has recently been created in the Belgian Congo by the free University of Brussels.

Miss Emily Benziehausen has given the Pittsburg Children's Hospital one million dollars for the investigation of diabetes in children.

An institute for investigation of the cause of influenza has been founded at Budapest.

The Budapest correspondent of the *Daily Telegraph* states that by a decree of the Minister of the Interior inoculation against diphtheria has become compulsory in Hungary. No conscientious objections will be allowed. Every Hungarian child must be inoculated—free of charge—at the age of 2 and again at the age of 6.

A monument has been erected in Rio de Janeiro to the memory of Professor Miguel Conto, who was president of the National Academy of Medicine for twenty years.

EPIDEMIOLOGY AND VITAL STATISTICS

No. 51

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended December 25, 1937. Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Irish Free State. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 125 great towns (ii) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns (iii) in Northern Ireland. (d) The 13 principal towns (ii) in the Irish Free State. (e) The 10 principal towns (iii) in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

22 Gas Masks and Cardiovascular Disease

H. LUCKE (*Dtsch. med. Wschr.*, November 26, 1937, p. 1797) draws attention to the dangers of gas-mask exercises for persons who, after a certain age, may be suffering from hitherto undetected cardiovascular disease. When, in addition to the application of a gas mask, the person wearing it is called on to perform certain duties entailing physical exertion the strain may be too much on the powers of adaptation, particularly if he is suffering from coronary disease. Professor Lucke's first patient was a man, aged 60, who developed typical angina pectoris. Medically examined nine weeks after the gas-mask exercises, an electrocardiographic test showed no abnormalities of the heart, and his blood pressure was normal. There were, however, signs of sclerosis of the aorta and emphysema. After six months he recovered. Much more serious were two other cases. The ages of the men were 53 and 60, and in the first case the wearing of a gas mask for only about fifteen minutes provoked sudden and violent pain in the chest associated with a sensation of suffocation. Although the mask was promptly removed, attacks of angina became daily worse, and the patient was unable to resume his work as a tailor. He was found to be suffering from marked cardiac insufficiency. The electrocardiographic findings were suggestive of coronary disease, and x-ray investigations showed considerable sclerosis of the aorta. No improvement followed, and he continued to be unfit for work. The third case was remarkably similar to the second, and in all three cases there had been no signs of coronary disease till the gas-mask exercises provoked them.

23 Expiratory Index in Tuberculosis

G. L'ETTORE and F. BAGNOLI (*Riv. Patol. Clin. Tuberc.*, October 31, 1937, p. 721) discuss the variations in the expiratory index—a ratio between the range of movement of the chest wall in expiration and in inspiration—in pulmonary tuberculosis before and after collapse therapy. The authors, after examining 162 cases classified according to their constitutional type and the various forms of tuberculosis from which they were suffering, come to several conclusions. (1) The expiratory index is definitely higher in the affected lung. (2) It is higher in the infiltrative and exudative forms of tuberculosis, especially in the case of recent lesions. (3) In subjects with an old lesion the appearance of recent infiltrative changes in the opposite lung gives rise to a higher expiratory index in the secondarily affected lung. (4) After phrenic avulsion or the induction of a pneumothorax the expiratory index is raised on the treated side, since in these cases inspiration is almost absent or very slight (at most 1 cm.), whereas expiration remains unaltered. (5) In some cases in which there was no active inspiratory movement but good expiratory movement it was nevertheless found possible to establish an efficient artificial pneumothorax. During the course of their investigations the authors also found that respiratory movements are greatest at the margins of the lungs and least at the apices, which accords with Forlanini's findings.

24 Meningo-encephalitic Complications of Rubeola

E. ADLER (*Hygiea*, October 31, 1937, p. 774) gives an account of an epidemic of rubeola which occurred in Sweden in the late winter and spring of 1937, and in which two cases with meningo-encephalitic manifestations were observed. The first patient was a girl of 16, who, on the eighth day of the rash, suffered from vomiting and headache. About a week later she became drowsy

and lost some control over her bladder. Loss of muscular tone, ataxia, and a mask-like cast of her features developed, and there were various abnormal reflexes. All these indications of meningo-encephalitis had disappeared after two months. The other patient was a girl, aged 12, who, on the sixth day of the rash, suffered from headache, vomiting, and giddiness. A day later epileptiform convulsions were associated with almost complete loss of consciousness, followed by a phase of agitation. Recovery in this case also was complete. In both there was a rise of the albumin and cell content of the cerebrospinal fluid. The author has collected twenty similar cases from the literature, and has found that the meningo-encephalitic symptoms have usually appeared between the sixth and seventh days of the rash. This complication of rubeola seems to be most common in young persons, females suffering more often than males. As a rule the temperature was normal between the appearance of the rash and the onset of meningitis, which was ushered in by fever lasting only a day or two. Common to all these cases was the completeness of the recovery in spite of the alarming character of the symptoms.

Surgery

25 Brauer's Precordial Thoracotomy

B. THÉODORESCO and N. VISINEANU (*Arch. Mal. Cœur*, September, 1937, p. 689) advocate, in view of six recent cases, a wider application of Brauer's precordial thoracotomy in cases of irremediable cardiac insufficiency. Often too much is expected from the operation in patients already moribund, in those in which it fails to prevent a cardiac lesion from progressing, or in other cases when it is not really indicated. In their series the authors had no deaths, although the operation was performed in patients who were all seriously ill. They believe that the major indication for the operation is grave cardiac insufficiency with enlargement of the heart. The presence of pericardial adhesions is a less important indication. Operation must be postponed if a progressive rheumatic lesion is present. Before operation an injection of morphine should be given, and combined local and regional anaesthesia should be used. Costal resection should be extensive in order to prevent recurrence of the cardiac insufficiency. Post-operative treatment is important. The operation does not cure cardiac lesions but enhances the functional capacity of the heart. Cardiac stimulants which before operation are "valueless" are "reactivated" after it.

26 Pelvic Neuralgia

J. RIBE (*Ann. bras. Gynec.*, October, 1937, p. 335) finds that obstinate neuralgia is often a predominant symptom in the evolution of malignant tumours, particularly of the pelvis, and among these neoplasms of the cervix are most common. When these tumours are themselves inoperable and the intense pelvic neuralgia cannot be relieved by analgesics, then the following palliative operations may have to be considered: (1) sympathectomy; (2) chordotomy, in which the best results are achieved by division of the anterolateral tracts; (3) the subarachnoid injection of alcohol. Unfortunately the conduction of pain from the pelvic region may be by one or more of several paths; hence the unsatisfactory and transient nature of the results obtained by peripheral operations, such as sympathectomy or resection of the presacral nerve. Moreover, since cancer is essentially invasive, it has only to spread to other parts of the cerebrospinal system for severe pain to make a renewed appearance. A more

Letters, Notes, and Answers

QUERIES AND ANSWERS

Painful Tongue

Dr. S. M. GRÓSZ (Budapest) writes in reply to "Worried" (*Journal*, December 18, 1937, p. 1259): The case seems to be one of Möller's superficial glossitis, as pernicious anaemia may be excluded. Though there was no response to ovarian extract, the possibility of a climacteric origin should not be overlooked; some gastric disturbance may also be of aetiological significance. As a mouth-wash I should recommend huckleberry tea, made from 250 grammes of huckleberries in 1.5 litres of water, inspissated to half this volume and squeezed out; its frequent use is of greater value than the application of silver compounds. Concerning general treatment, I recommend the intravenous administration of vitamin C, suggested by Volhard. I would like to hear from "Worried" if this treatment has any effect.

Income Tax

Supplementary Reserve Commission Gratuity

"EPSILON" inquires whether an annual gratuity of about £25 falls within the non-taxable class of gratuities referred to in a note which appeared in the *Supplement* of November 7, 1936.

No. "Epsilon's" gratuity is an annual payment made in connexion with an express or implied contract for service and as such is liable to income tax. The gratuities which we explained were not taxable are lump sum payments made on cessation of an appointment, and though arising out of the service rendered cannot be regarded as "annual," and are therefore not assessable to tax.

LETTERS, NOTES, ETC.

Chlorine Mixture for Typhoid

Dr. ALEXANDER FRANCIS (London, W.1) writes: I would strongly advocate the giving of Burney Yeo's chlorine and quinine mixture to all typhoid fever suspects. There is much doubt as to the advisability of administering T.A.B. vaccine in such cases, but the chlorine mixture is absolutely harmless and safe. I had very considerable experience of the treatment of typhoid fever when in charge of a hospital in the west of Queensland, where typhoid was very prevalent. Many of the cases were desperate, because the bushmen made of the cases and would not come to hospital until the light of illness and would not come to hospital until the second or third week of the disease, after all home remedies, including "trying to ride it off," had failed. From the time I made use of Burney Yeo's chlorine mixture I was fortunate enough not to have a fatal case, and some of the recoveries in patients who were brought to hospital in the "typhoid state," delirious, with tongues like boiled leather and with sordes on the lips, were amazing. It is a common practice to chlorinate water in order to destroy the typhoid bacillus,

and if chlorine mixture were given to suspects it would almost certainly prevent the disease from developing, and at all events make an attack much less severe. It is important that the mixture be made according to Burney Yeo's directions.

** The instructions quoted in Martindale's *Extra Pharmacopoeia* are as follows: *Mistura Chlori cum Quinina* (Burney Yeo). To potassium chlorate, in powder, 30 gr., in a 12-oz. bottle, add hydrochloric acid 60 m.; cork and shake well to liberate chlorine; absorb this by gradually adding, and shaking after each addition, distilled water q.s. to 11 oz.; and quinine sulphate 24 gr. (or 36 if ordered), syrup of orange 1 oz. Dose.—1 oz. (30 ml.) every two, three, or four hours for typhoid; it quickly cleanses the tongue.

The Quintuplets and their Doctor

On May 28, 1934, Mrs. Elzire Dionne, a young French-Canadian living in a settlement two hundred miles north of Lake Ontario, gave birth to five living girls. Dr. Allan Roy Dafeo of Callander arrived after the birth of two of the infants, but was present during the delivery of the remaining three and took charge of the whole situation. The progress of the Dionne quintuplets has been a subject of world-wide publicity almost from the date of their birth. In the *Canadian Medical Association Journal* for November, 1937, Drs. A. R. and W. A. Dafeo reported that at 3 years the

children had reached an average weight of 30 lb. 8 oz.—at birth it was 2 lb. 11 oz. In general their health and physical development has been satisfactory. Two years ago we reproduced in this column a Christmas and New Year card showing the "quins" and their doctor at play on the nursery floor. Dr. A. R. Dafeo now sends us, with the compliments of the season, a contemporary group taken beside the self-contained wooden house where the children live under State care and protection; beneath the photograph is a little view of their home.

Cambridge Medical Women

The writer of a letter published in the *Sunday Times* of January 2 said with reference to Cambridge medical degrees: "Though women are admitted with men to this examination and take the same papers and viva voce, and appear, if successful, in the same lists as men, yet they are not recognized by Cambridge University as having taken the degree and they are not entitled to add M.B.(Cantab.) after their names. They are not entitled, for instance, to make use of those words on a brass plate." This is incorrect. A woman who has received the title of the degree of M.B. from the University of Cambridge may add "M.B." to her name on her professional diploma or elsewhere; and in fact "M.B." is added to her name in official lists published by the University.

Local Application of Prontosil Red

Dr. J. F. P. GALLAGHER writes: I have obtained excellent results in the treatment of erysipelas and acute dermatitis by using as a local application prontosil red, 7½ grains dissolved in 1 oz. of distilled water. The value of this preparation as an external application should not be overlooked.

long period, while others do better with a smaller total dose made up of large daily doses given within a short period. Carcinomata of the larynx can be classified according to the results obtained from radiotherapy. Relatively mobile tumours consisting of non-differentiated cells benefit from large total doses spread over a long period, as well as from smaller total doses given within a short period. Fixed tumours consisting of well-differentiated and infiltrating cells are not always influenced by an increase of the total dose; on the contrary, this technique may sometimes render the tumour radio-resistant. The author concludes that there are two main forms of radiotherapy: (1) the quantitative simple, elementary therapy, the two main factors of which are the total dose and the continued treatment; and (2) qualitative radiotherapy, which is physiological and the two main factors of which are very large daily doses given at appropriate times and the periodicity of the treatment, which is non-continuous.

32 Loss of Taste after Mastoidectomy

WAYNE, Y. H. HO (*Arch. Oto-laryng.*, Chicago, August, 1937, p. 146) describes the clinical methods of testing the perception of taste. The following aqueous solutions were used as testing reagents: 5 per cent. solution of cane sugar for sweet taste; 10 per cent. solution of sodium chloride for salty taste; 1 per cent. solution of acetic acid for sour taste; and 1 per cent. solution of quinine sulphate for bitter taste. The tip of the tongue is exceptionally sensitive to sweet taste, the side of the tongue to the other tastes. Six cards with the following words are held in front of the patient: sweet, salty, sour, bitter, no taste at all, peculiar taste. When the tests are made he is instructed to point out on the card which the taste is. Whenever the facial nerve is divided within the bony canal above the point where the chorda tympani leaves it taste is lost over the anterior two-thirds of the tongue. In persons who had undergone a radical mastoid operation loss of taste was invariably found. None of these patients had noticed any change of taste subjectively because the involvement is unilateral. Other conditions investigated were acute otitis media, chronic middle-ear suppuration, and fracture of the skull.

33 Exocranial Complications of Petrous Suppuration

R. MASPÉTIOL (*Ann. Oto-laryng.*, September, 1937, p. 790) divides these rare complications of middle-ear suppuration into three groups. A first group of sublabrynthine osteitis, in which the abscess reaches the surface in the region of the lower opening of the carotid canal. The infection spreads along the sheaths of the vessels and becomes a latero-pharyngeal abscess. A second group of "apicitis," in which the abscess breaks through actually into the wall of the pharynx. Clinically such cases present inflammatory swellings along the Eustachian tube or in the soft palate. A third group, in which the abscess reaches the surface of the petrous bone above the labyrinth. If the infection breaks through to the surface of the skull instead of becoming subdural a temporal or occipital abscess results or an abscess beneath the sterno-mastoid muscle. The pathology is distinct from that of Bezold's abscess, where the suppuration spreads from the mastoid cells. The exact localization of the suppurative focus in the petrous bone can be deduced from the localization of these peripheral abscesses. The clinical features and treatment are described separately for each group. A neck incision for draining the abscess is usually necessary, unless it opens spontaneously into the pharynx. Anatomical experiments were made in order to study the pathway taken by the pus. Some of the bone beneath the labyrinth was removed with a gouge. A hole was then made with a drill until the petrous bone was just pierced on the lower surface. Then a few cubic centimetres of plaster-of-Paris were injected under pressure. This accumulated invariably around the internal

jugular vein or internal carotid artery and a swelling occurred in the neck. In the second and third groups experimental proof was much more difficult to obtain.

34

Laryngeal Stenosis

R. LUCHSINGER (*Schweiz. med. Wschr.*, November 6, 1937, p. 1065) discusses the treatment of the respiratory and speech difficulties in cases of midline fixation of both vocal cords as a result of bilateral paralysis of the recurrent laryngeal nerve. A number of workers recommend the operative repair of the stenosis, while others rely on conservative treatment or on a combination of tracheotomy and the application of a speech cannula and conservative treatment. An entirely new method of treatment was suggested by Froeschels. It consists of "explosive jerks" exercises (*Stossuebungen*) for the vocal cords. Of the eleven cases reported by the author ten were treated successfully by a combination of tracheotomy, a valve cannula, and exercises by Froeschels's method, while one case was treated successfully with vocal exercises alone. The author recommends the carrying out of functional vocal and respiratory tests in every case before and after the operation, so that the results of the operation may be properly assessed.

35

Lengthening the Nasal Septum

M. W. MOOTNICK (*N.Y. St. J. Med.*, September, 1937, p. 1509) describes a new plastic operation which is indicated in cases where the columella is drawn up and either the tip of the nose or the alae project too far down with a resulting ugly outline of the face. An incision is made in the midline of the columella, and through this incision the cartilage of the septum is stripped of mucoperichondrium on each side, as in a submucous resection. But the elevation of the mucoperichondrium is carried upwards for a distance of only 3 cm. on one side and for 2 cm. on the other side—an important point in the operation. The next step is to make two parallel incisions in the covering of the septal cartilage by way of the nares. These incisions begin at the lower edge of the cartilage at the anterior and posterior ends of the columella, and extend upwards for 3 cm. on the one side and 2 cm. on the other side. The two parallel incisions are then united by a third incision, which joins their upper ends. The columella is thus liberated and may easily be lowered to the desired position, the rectangular flap of mucoperichondrium descending with it. The columella is anchored in the new position by two mattress sutures passing through the mobile septum at the lower end of the septal cartilage. A few more stitches are used to hold the septal flap in position and the columella incision is closed. Owing to the difference in length of the incisions on each side the denuded areas of the septum do not occur at the same level. The cartilaginous septum is not deprived completely of its nutrition at any point and the exposed areas heal nicely by granulation followed by smooth scarring.

Obstetrics and Gynaecology

36

Endometriosis

J. NOVAK (*Med. Klinik*, October 22, 1937, p. 1424), in a description of the histology of extra-uterine endometriosis, points out that the islets of endometrioid tissue contain typical uterine glands, usually but not always surrounded by the tissue in which they are embedded in their natural site, which tissue undergoes decidual transformation during the premenstrual phase and pregnancy. Occasionally heterotopous foci contain smooth muscle, and not infrequently certain of them consist of the characteristic cytogenous tissue only. The heterotopous endometrial islets undergo cyclical menstrual changes: the result of their intraperitoneal discharge of blood is the formation of

radical operation, such as chordotomy, is therefore necessary to interrupt the centripetal fibres of both the vegetative and the central nervous system. Two examples of this operation are given. In the first patient the anterolateral tract was cut through on both sides at a distance of one segment apart. Both pain and thermal sensation were abolished, but a remarkable dissociation of sensibility occurred, since analgesia was complete below the level of the ninth dorsal segment on one side and tenth dorsal segment on the other, whereas thermal sensation was only affected from the knee downwards. This patient was completely relieved of all pain for the seven months before her death. The operation in the second case, however, was a complete failure, for though bilateral chordotomy was also performed the section was intentionally not so deep, and the highest level of analgesia was at the twelfth dorsal segment and thermal sensation was unaffected. The patient was relieved for a few days only, after which the pains returned.

Therapeutics

27 Fresh-air Treatment of Pneumonia

1. JOCHIMS (*Med. Welt*, November 27, 1937, p. 1663) has observed in children's wards the effect of pure, gently moving, cool or warm, moist or dry, air introduced into a special "weather chamber" containing two cots. Sick-room air which is too warm and moist quickly produces restlessness and limpness, and the good effect of transferring the patients to the cool-air chamber is notable. Without giving figures Jochims confirms the conclusion of Degkwitz and of Wallace (*British Medical Journal*, 1937, 1, 657) that nursing pneumonia patients in fresh air considerably diminishes the mortality; he prefers to continuous fresh-air treatment, however, alternation of periods of five to six hours in cool conditions with similar periods in a warmer, closed apartment. The alternating treatment, he finds, throws less strain on the circulation and permits, with less disturbance, the nurse's observation and attentions. A favourable effect of alternating treatment is observed, half an hour after replacement in warm surroundings, in an increase of 3° to 5° C. in the surface temperature of the unclothed parts, which increase lasts for four to five hours. Jochims has also found, by measuring the area of moistening of a metal plate by the patient's expired air, that in the cold chamber nasal respiration is greatly facilitated. The freedom from dust of the chamber air is another beneficial factor. During the cool period the child is well packed in a warmed bed, wearing a woollen cap: the range of air temperature is 10° to 14° C. The duration of the fresh-air treatment is shortened if signs of cardiac weakness or cyanosis are noted; it is unsuitable for premature and other infants inclining to low temperatures, and needs special care when spasmophilic patients are concerned.

Haematemesis and Melaena

28 Haematemesis and Melaena

E. MEULENGRACHT (Münch. med. Wschr., October 1, 1937, p. 1565) relates his further experience with an unrestricted diet in the treatment of 368 cases of acute or chronic gastric or duodenal ulcer complicated by haematemesis or melaena. The patients received food and drink on the first day after the haemorrhage. The food was semi-liquid and was given five times a day. Alkalis, atropine, and iron were given at the same time. This rule was particularly enforced in cases in which the haemorrhage had been very severe. The patients were allowed to move in bed and to get up after fourteen days. Under this treatment the patients fared much better than under the old starvation regimen. Their strength returned and the regeneration of the blood was more rapid, while the period of convalescence was shortened. There was no exacerbation of the haemorrhage as a result of the diet. The mortality from haemorrhage decreased from 7.9 per cent. to 1.3 per cent.

Laryngology

29 Blocking the Recurrent Laryngeal Nerve

R. SEGRE and A. JACHIA (*Minerva med.*, November 4, 1937, p. 485) carried out surgical blocking of the recurrent laryngeal nerve in four patients suffering from tuberculous laryngitis. All the cases showed circumscribed lesions of the left half of the larynx, mostly of an ulcero-infiltrative character affecting the true and false vocal cords. They had all been treated previously by various methods, including the galvanocautery. One patient also showed perichondritis of the arytenoid cartilage. The pulmonary lesions were slight and stationary, although the sputum was positive. The operation was carried out under local anaesthesia. In three cases an oblique incision was made along the anterior border of the sterno-mastoid, and in one (a young lady) a transverse incision was made for aesthetic purposes along the upper border of the clavicle. The nerve was then exposed and ligatured with catgut. During the first few days after the operation there was complete aphonia, the voice gradually improving in the course of a month until it became quite normal. About a fortnight after the operation the ulcero-infiltrative lesions slowly but progressively subsided.

30 The Sphenoidal Sinus

F. W. DIXON (*Ann. Otol., etc.*, St. Louis, September, 1937, p. 687) presents an anatomical study of the sphenoidal sinuses based on the examination of 1,600 skulls. The two sides rarely develop symmetrically. It is not uncommon to find one sinus rudimentary while the other is well developed and invades the lesser wing of the sphenoid and the pterygoid process. In 7 per cent. of the skulls the optic nerve was so deeply embedded that it appeared as a cylindrical ridge in the interior of the sinus. In such skulls only a thin plate of bone covered the nerve and bony dehiscences occurred frequently. The lateral wall sometimes showed a cylindrical indentation due to the internal carotid artery. In 1 per cent. of the sinuses there were dehiscences with the internal carotid artery clearly seen on the lateral wall. The volume capacity of the sinuses varied enormously, from 0 to 14 c.cm. on each side. When the sinuses were considered in age groups it was found that there was no increase in the size of the cavity after puberty. Bony septa in the sinuses were found in 32 per-cent. of skulls. These sprang from every surface and occurred in every conceivable variation, dividing the cavities into medial, lateral, superior, inferior, anterior, and posterior cells. Such anatomical conditions would seriously interfere with drainage. Many of these subdivisions of the sphenoidal sinuses were due to abnormally placed posterior ethmoid cells. In fifty-five skulls in this series an abnormally placed ethmoid cell occupied the upper part of the sphenoidal sinus and had pneumatized the space about the optic nerve and partially enclosed it. Therefore in optic neuritis the rhinologist must consider both the ethmoid and the sphenoidal sinuses.

31 X-Ray Therapy of Laryngeal Carcinomata
September, 1937

31 X-Ray Therapy of Laryngeal Carcinoma. H. COUTARD (*J. Radiol. Électrol.*, September, 1937, p. 462) stresses the diversity of the histological structure of carcinoma of the larynx. This diversity is responsible for the inconstant results of x-ray therapy—for example, out of the nine cases treated in 1932 six patients were alive after five years, thus giving 66 per cent. of five-years cure, whereas of the cases treated in 1931 only two out of seven (28 per cent.) were alive after five years. The author gives a detailed account of the evolution of his radiotherapeutic technique. He believes that the therapeutic results are determined by three main factors: (1) the total dose of x rays; (2) the daily dose; and (3) the appropriate variations of the intensity of the daily doses. Certain cases benefit from relatively small daily doses spread over a

dense adhesions, that of encapsulated accumulation of blood the production of chocolate or tarry cysts. Endometriosis is more familiar to the gynaecologist than the general surgeon, and is probably the cause of many acute intraperitoneal haemorrhages coming to operation for supposed acute appendicitis and then attributed to "corpus luteum haemorrhage" or an unknown source. Extension to the rectum from the pouch of Douglas may closely simulate a rectal cancer with stenosis, but the mucosa, though distorted, is not invaded. Considering the pathogenesis of endometriosis, Novak accepts Sampson's implantation theory, and remarks that retrograde transfer of menstrual blood and fragments through the tube has been proved. That other modes of production occur is shown by the occurrence of foci of endometriosis in the lymph glands and round ligament, and even in the limbs (the thigh and the forearm muscles in two recent reports). Probably certain foci are formed locally from the peritoneal epithelial or subepithelial tissue, and transmission is effected in certain cases in lymph or blood vessels. Novak regards the result of operative treatment, unless the whole of the uterus and both ovaries are removed, as uncertain. In the case of extensive endometriosis of the recto-vaginal or vagino-vesical septum complete resection of the endometrioid tissue is technically very difficult; removal of the uterus and ovaries is fortunately followed by shrinkage of that portion of the tumour which is left behind, so that the severe pain is cured.

37 F. C. VAN TONGEREN (*Zbl. Gynäk.*, October 16, 1937, p. 2422) in his last 200 laparotomies at the Amsterdam Women's Hospital (Caesarean operations and cases of general peritonitis excluded) found endometriomata in no fewer than twenty-eight patients. The twenty-two cases in which it had been unsuspected included twelve of uterine fibromyomata out of ninety-four cases of this condition. A contributing factor in diagnostic errors is the variability of the intensity of menstrual pain; dysmenorrhoea may be so severe as to lead (as in two of these cases) to an initial diagnosis of acute appendicitis, or may be slight in comparison with the chronic intermenstrual pain. Operative treatment is preferred and is done on conservative lines; in ovarian endometrioma simple resection is undertaken, and has been followed in two patients, previously sterile, by pregnancy going uneventfully to term. Irradiation with x rays is thought to be suitable in patients nearing the menopause who have small tumours and dysmenorrhoea as the sole symptom. Van Tongeren describes in detail cases of endometrioma of (1) the round ligament, which was adherent to the Fallopian tube, (2) the external abdominal ring, and (3) the perineum. In the last-named situation endometrioma is very rare, and in most cases has affected the site of repairs after labour; here, however, it occurred on each side, as a tender bluish nodule, in the scars following lateral incisions for vaginismus. No recurrence has followed in the two years since excision.

38 Delivery of Over-weight Babies

E. HAUCH (*Hospitalstidende*, November 2, 1937, p. 55) classes as over-weight those babies which at birth weigh more than 4,500 grammes. In his maternity hospital in Copenhagen 191 babies weighing 4,500 to 5,000 grammes were born in the course of about 25,000 confinements. There were thirty-two babies whose weight at birth ranged from 5,000 to 6,000 grammes, and only five whose weight at birth exceeded 6,000 grammes. In the course of twenty-six years Professor Hauch has observed among 42,500 babies six weighing 6,000 grammes or more—a rate of 0.0014 per cent. In four cases the head was born spontaneously, and only in two did its extraction require forceps. Much more difficult was the birth of the shoulders, which was effected by expression alone in only one case. In all the other cases an arm had to be pulled down. All but one of the babies were males. After describing in detail the manoeuvres to be attempted in

delivering such over-weight babies, the author notes that Caesarean section seldom solves the problem, for its true character is usually not recognized till the head has already been born. It is most difficult to diagnose overweight in a child before serious obstacles are encountered to the delivery of the shoulders. This complication may, however, be suspected if confinement is long overdue, and in one of the author's cases pregnancy had gone three weeks beyond term. He has in many cases induced labour when he has suspected that the child was becoming too big or when pregnancy had gone beyond term, and he believes that by a most careful supervision of pregnancy it should be possible to anticipate the birth of some over-weight children at least by the artificial induction of labour.

Pathology

39 Testosterone and the Female Genital Tract

G. COTTE, J. F. MARTIN, and E. MANKIEWICZ (*Gynécologie*, October, 1937, p. 561) have examined the action of testosterone propionate on female rabbits. Cotte and Noël have previously shown that testosterone acetate, in rabbits, (1) inhibits the sexual cycle of the non-castrated animal, preventing follicular ripening and luteinization, and (2) lacks the capacity of folliculin to induce rut in the castrated animal. The propionate has a five times greater biological activity, but in the castrated rabbit produces no secretory phenomena in the endometrium. On the other hand, it has a well-marked effect on stroma cells, producing sclerotic changes in the ovary and uterine cornua, and sclerosis and cyst formation in the mammary gland. In the ovary, ovulation is profoundly disturbed and many atretic follicles are seen; these changes are probably brought about through the hypophysis. Arrest of uterine haemorrhage has been reported by Mocquot and Palmer after therapeutic administration of testicular hormone.

40

Vitamin C Content of Milk

B. HANNISDAHL (*Tidsskr. norske Laegeforen.*, October 15 and November 1, 1937, pp. 1068 and 1111) has investigated the vitamin C content of cows' milk, testing it quantitatively for ascorbic acid under various conditions. Wide fluctuations in the ascorbic acid content of the milk were found, and they evidently depended on the quality of the fodder, the mode of transport of the milk from cow to consumer, and the length of the interval between milking and consumption. Some of the milk was obtained from stall-fed cows, some from cows whose stall feeding included green fodder, and some from cows at pasture. These investigations extended from the beginning of May till the middle of July, 1936. During this period there was on the whole a rise in the ascorbic acid content of the milk, which fluctuated between 1.7 mg. of ascorbic acid per litre to 11.7 mg. The lowest figures were found in the oldest supplies of milk, the highest in the milk whose itinerary between cow and consumer was the shortest. The use of transparent glass vessels for the transport of milk also played a part in determining the ascorbic acid content of the milk, which varied according as these vessels were kept during transport in a wagon or allowed to travel on its roof, fully exposed to sunlight. Under the latter conditions the ascorbic acid content of the milk varied according as the weather was cloudy or sunny. Milk from pasture-fed cows contained more ascorbic acid than that from stall-fed plus green-fodder-fed cows, and still more than from the exclusively stall-fed cows. But even under the best conditions the author comes to the conclusion that milk does not contain enough ascorbic acid to meet the vitamin C requirements of the human body when one litre of milk is consumed per day. Other sources of vitamin C must, therefore, be drawn on in a town such as Oslo, where the consumption of milk per head is only 0.58 litre.

**"ALMOST INSTANTANEOUS RELIEF IN THE
SEVEREST ATTACKS OF ANGINAL PAIN"**

Euphyllin, administered intravenously, will check severe Anginal pains, even during the injection.

Euphyllin dilates the coronary and kidney vessels, greatly increases the rate of flow of blood through the heart, and improves the mechanism of exchange between the blood and the tissues.

Euphyllin is a non-mercurial diuretic of great potency and can therefore be recommended for oedema, uremia, eclampsia, etc.

TRIVALIN

THE FINEST ANODYNE

(Supplied solely to the Medical Profession)

In ampoules for injection, capsules and Tablets

Extracts from Clinical Reports:

Cancer. "I have used Trivalin with most satisfactory results in Carcinoma of the Mamma. No preparation I have tried, including Morphia (which produced vomiting), gave so much relief."

"I consider the addition of Hyoscine valuable in Morphia suppression, and have found the combination valuable in hysterical frenzies and other forms of mental excitement."

"I shall continue to use it when Morphia is indicated, and particularly when Morphia-action is indicated but Morphia itself contra-indicated."

"HEPATAGEN"

(MIST. HEPATICA CONC. HEWLETT)

COMPOSITION—Ext. Cascarae, Ext. Rhei, Jalapin, Podophyllin, Cocainae Hydrochlor., 1-20th gr. in each fluid drachm.

This preparation does not come under the Dangerous Drugs Act.

A POPULAR remedy for Chronic Biliousness, Catarrhal Jaundice and the Jaundice of simple Hepatic Torpor. In passive or habitual Congestion of the Liver it has been used with marked benefit.

In the treatment of acute or temporary constipation in convalescents and in pregnancy, or in the constipation due to sedentary habits, to a deficiency of intestinal secretion and of peristalsis, the mixture can be prescribed with wonderful effect.

The dose is from 10 to 60 minims, according to the age and condition of the patient. One drachm is a direct aperient and is not accompanied by griping or tenesmus.

This preparation is also supplied "sine Cocaina," the dose and price remaining the same.

PENSIONS & INSURANCE

FOR

MEDICAL

PRACTITIONERS

The Insurance Acts Committee of the British Medical Association acting as the executive body of the Conference of Representatives of Local Medical and Panel Committees after protracted investigation, recommended to all Insurance Practitioners a

Pension and Insurance Scheme providing

- (a) Pension at age 65
- (b) Disablement Income
- (c) Family Protection

The extraordinarily low rates quoted are available only until

September, 1942

but policies effected prior to that date will not be affected by any alteration made thereafter.

The Council of the British Medical Association resolved that this scheme should be made available also to members not engaged in National Health Insurance practice.

These policies are issued through the Medical Insurance Agency of B.M.A. House, Tavistock Square, acting as agents of the Insurance Offices for the collection and receipt of quarterly premiums.

Other insurances, Motor, Household, Educational, etc., are also available at specially favourable rates.

In this, as in all else,

THE M.I.A. EXISTS TO PROTECT YOUR INTERESTS AND SAVE YOUR MONEY.

HALF ACTUAL SIZE

TRADE IRISE MARK

"IRISE" EYE LOTION BATH

THE IRISE Eye Bath is built up of two parts. The top part is made of rubber and the lower of white glass. Hitherto, eye baths have been available only in either glass or rubber alone. The rubber variety were advantageous because they prevented leaking of the lotion down the face during the application to the eyes, but being opaque, were not easily cleansed. On the other hand, when made wholly of glass, leaking down the face occurred and they were not so comfortable when applied to the skin as the rubber variety.

The IRISE Eye Bath combines the advantages of both patterns without their disadvantages. The rubber eyepiece allows the user to open and close the eyelids whilst the lotion is being applied, without leaking or being uncomfortable, and the lower glass reservoir, being transparent, gives visibility and is easily cleansed.

If it is desired to disconnect the two pieces, they are best connected again whilst immersed in clean water.

The IRISE Eye Bath can be purchased direct, post free, 1/-, from the manufacturers or through chemists.

CELLANBAND

ANTISEPTIC PASTE-IMPREGNATED
BANDAGES

The CELLANBAND Dressing, when properly applied, furnishes a mechanical support vastly superior to crepe or rubber bandages, elastic hosiery, etc., and will usually be found sufficiently robust to enable the convalescent to resume reasonable light duties at an earlier period. CELLANBAND Dressings exercise a marked dehydrating and antiphlogistic effect, resulting in rapid reduction of oedema. Air-access to the tissues is not interfered with as in the case of gelatine dressings, so that evaporation of the skin secretions continues normally.

12/- PER DOZ. (7 yds. long, 4in. wide)
SAMPLE BANDAGE 1/- POST FREE

'SANOID'

STERILIZED LIGATURES

These ligatures are British both in production and materials. Their Tensile strength is well in excess of the recognised standards for particular sizes. A special process gives a surface-finish that ensures easy manipulation. SANOID Ligatures are exceedingly supple, the catgut straightens out and remains straight without "kinks" which are liable to cause breakage. Sterilization is carried out by the most up-to-date methods, and independent Bacteriological tests over several months in all cases gave negative results. Exceptional elasticity lessens the risk of necrosis.

WARM, DRY BEDS FOR OPERATION AND ACCIDENT CASES

In cases of sudden emergency and for everyday use, the "Thermega" Electrically-Heated Blanket is invaluable for providing warm, damp-free beds. Hospitals and Nursing Homes throughout the country use "Thermega." It is the one proven remedy for driving out dampness and ensuring warm beds at the turn of a switch.

The "Thermega" Electric Pad for local application is ideal for relief of pain.

At all good stores, chemists, electricians; or from Thermega Limited, 51/53, Victoria Street, London, S.W.1.

Railway Stations at Gloucester, the Hospital is easily accessible by rail from London and all parts of the United Kingdom. It is beautifully situated at the foot of the Cotswold Hills, and stands in its own grounds of over 300 acres. Voluntary Patients of both sexes are also received for treatment. Special accommodation for Lady Voluntary Patients is also provided at the MANOR HOUSE, which has its own private grounds and is entirely separate from the Main Hospital. For particulars as to terms, etc., apply to G. W. T. H. FLEMING, M.R.C.S., L.R.C.P., D.P.M., Medical Supt. Telephone: No. 6207 Barnwood.

**CITY OF LONDON MENTAL HOSPITAL,
DARTFORD, KENT.**

Ladies and Gentlemen received for treatment under certificates, and without certification, as either VOLUNTARY or TEMPORARY PATIENTS. At a weekly fee of TWO GUINEAS and upwards.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupational Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres, Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park. At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc.

For terms and further particulars apply to the Medical Superintendent (Telephone Nos. 2356 and 2357 Northampton), who can be seen in London by appointment.

HAYDOCK LODGE

NEWTON-LE-WILLOWS, LANCASHIRE

Telegr.: Street, Ashton-in-Makerfield.

HOSPITAL FOR MENTAL DISEASES

This Institution is exclusively for the reception of a limited number of Private Patients of both sexes of the Upper and Middle Classes at moderate rates of payment. It is beautifully situated in its own grounds on an eminence a short distance from Nottingham, and from its singularly healthy position and comfortable arrangements affords every facility for the relief and cure of those mentally afflicted. Occupational Therapy. Voluntary and Temporary Patients received.

Tel.: 64117. For terms, etc., apply to the Medical Superintendent.

To relieve PROSTATE GLAND TROUBLE in ELDERLY PEOPLE

It has long been recognised by the Medical Profession that applications of small continuous electrical currents frequently give relief in the distressing cases of too frequent micturition, regarding which they are consulted by patients of advancing age.

The small apparatus illustrated is convenient for use by such patients under the direction of their Medical adviser, if in his opinion operation is inadvisable. The current provided by a small number of dry cells is conveyed through suitable convenient electrodes to the parts affected. Shock or accidental excess of current is absolutely impossible. The first cost and maintenance of the apparatus is very moderate.

HEALTH RESTORED *by* PINES-SUNSHINE & SEA AIR

The happy combination of these three health-giving properties have earned for Bournemouth an unrivalled reputation as a centre for convalescence, more especially in the case of pulmonary disorders. The weight of medical evidence to this effect is attested by the highest authorities, and should induce you to recommend this delightful town to your own patients.

The facts and figures relative to Bournemouth's health-giving attributes in the "Book of Bournemouth" will interest you. Write for it to the Publicity Manager, Room 109a, Town Hall, Bournemouth.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

INCORPORATING THE ROSS INSTITUTE.

POSTS OVERSEAS FOR MEDICAL MEN

A register is kept in the School of medical men who are prepared to be considered for posts overseas, and the School is frequently asked to advise plantation and mining companies when such posts fall vacant.

The salaries offered are attractive; conditions of service are governed by standardised forms of contract; and many of the posts offer to medical men a most interesting field in which to practise their profession.

It is desirable that candidates for posts overseas should hold a diploma in tropical medicine and hygiene. The course provided by the London School for the Conjoint Board's Diploma lasts six months and the tuition fee is £40. The course may be taken from October to March or from January to June. There are generally more vacancies in the course commencing in January.

The Director of the Ross Institute is always glad to interview medical men who would like information regarding the possibilities of a career overseas if they will be good enough to make an appointment to call on him. Enquiries may be addressed to

SIR MALCOLM WATSON, Director,
Ross Institute of Tropical Hygiene,
London School of Hygiene & Tropical
Medicine,

KEPPEL STREET, GOWER STREET, W.C.1.

ADVICE ON THE CHOICE OF SUITABLE SCHOOLS AND TUTORS

for BOYS and GIRLS with prospectuses of recommended establishments will be given free of charge to parents stating age of pupil, district preferred, range of fees and type of school required.

MEDICAL CORRESPONDENCE COLLEGE

19, WELBECK STREET, LONDON, W.1.

PROVIDES HIGHLY SUCCESSFUL ORAL AND POSTAL COACHING FOR ALL MEDICAL EXAMINATIONS.

Special Preparations for all Surgical Qualifications.

F.R.C.S. ENGLAND M.S. CANTAB.
(Primary and Final). M.S. LONDON.

F.R.C.S. EDINBURGH.

And all other Surgical Degrees and Diplomas.

* The remarkable success of Students of the Medical Correspondence College at the higher Surgical Examinations is specially noteworthy.

* Both at the Primary and Final F.R.C.S. England the majority of our Students are successful at the first attempt, and Candidates who have failed at these Examinations on several previous occasions set through without difficulty after going through our courses.

* The Surgical Tutors of the College all hold either the M.S. Lond., or F.R.C.S. England, or both, and are highly experienced teachers.

* The Postal Courses are thoroughly clear, concise, and up to date, and the test questions are carefully selected from those set at previous Examinations, so as to embrace all parts of the subject. By working systematically through the Course the Student is brought up to the examination standard in the minimum time, and much unnecessary reading is saved.

ROYAL NAVAL MEDICAL SERVICE.

Vacancies exist for Medical Officers in the Royal Navy, and applications are invited for entry in April, 1938.

Candidates below the age of 28 years are preferred, and they must be registered under the Medical Acts. No examination in professional subjects will be held, but candidates will be required to attend for interview by a Selection Board.

Selected candidates will be entered for Service for a period of three years in the first instance, which may be extended to five years at the discretion of the Admiralty.

At the end of three years' service officers may retire with a gratuity of £400, but those who serve for five years will receive £1,000.

At the end of five years' Short Service permanent commissions will be given to selected officers who wish to make the Naval Medical Service their permanent career. Officers transferred to the permanent list will receive a gratuity of £1,000 (less Income Tax).

Opportunities are available for officers on the permanent list to specialise, and ample provision is made for Post-Graduate study.

Copies of the regulations for entry and conditions of service, including rates of pay and allowances, may be obtained from the Medical Director-General of the Navy, Admiralty, S.W. 1, and from the Deans of all Medical Schools.

Applications for entry from intending candidates must be received not later than February 28th, 1938.

COUNTY BOROUGH OF CROYDON. PUBLIC HEALTH DEPARTMENT. ASSISTANT DENTAL SURGEON.

Applications are invited from male licentiates in dental surgery for the post of whole-time Assistant Dental Surgeon. The duties will consist chiefly in the inspection, re-inspection, and treatment of children attending the elementary schools of the Borough, but will also include dental work under the Council's Maternity and Child Welfare and Tuberculosis Schemes. The person appointed will also be required to give instruction in dental hygiene as and where required. Applicants must have had at least one year's previous experience in the dental treatment of children. The successful applicant will work under the supervision of the Medical Officer of Health and the Senior Dental Officer.

The salary will be £450 per annum, rising by annual increments of £25 to £500 per annum. The post is designated under the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and a deduction of 5 per cent. will be made from the salary. The successful candidate will be required to pass a medical examination. Canvassing will be a disqualification.

Applications on forms to be obtained from the Medical Officer of Health, Town Hall, Croydon, accompanied by copies of not more than three testimonials of recent date, must be returned to him not later than 11 a.m. on Monday, January 24th, endorsed "Assistant Dental Surgeon." The appointment is subject to two months' notice of termination on either side.

Town Hall, Croydon.
December 24th, 1937.

E. TABERNER.

Town Clerk.

METROPOLITAN BOROUGH OF ISLINGTON. Appointment of ASSISTANT MEDICAL OFFICER.

The Council invite applications from members of either sex whose age must not exceed 40 years for the appointment of an Assistant Medical Officer, whose duties will consist mainly of maternity and child welfare work, to be carried out under the direction of the Medical Officer of Health. The duties will include certain administrative work in the wards of two voluntary Welfare Centres, clinical work at the Council's Day Nursery, artificial sunlight treatment, diphtheria immunisation clinics, and such other duties in connection with maternity and child welfare and public health as may be required by the Council.

Candidates must be registered medical practitioners, with the Diploma of Public Health or Degree of Sanitary Science. They must also possess special children's and infants' experience and knowledge of the treatment of nutritional disorders of infancy, and previous experience of maternity and child welfare work, ultra-violet light therapy and diphtheria immunisation.

The salary for the appointment will be at the rate of £600 per annum, rising by annual increments of £25 to £750 per annum. The candidate appointed will be required to devote whole time to the duties of the office, and will not be allowed to practise privately. The appointment will also be subject to the rules and regulations of the Council from time to time in force relating to their officers.

Applications, accompanied by copies of not more than three recent testimonials, on forms to be obtained from the undersigned, must be delivered at the address stated below not later than Wednesday, January 26th, 1938, endorsed "Appointment of Assistant Medical Officer."

Canvassing, directly or indirectly, will disqualify. Town Hall, W. ERIC ADAMS.
Upper Street, N.1. Town Clerk.
December 30th, 1937.

CITY OF LEEDS. KILLINGBECK SANATORIUM. SENIOR ASSISTANT RESIDENT MEDICAL OFFICER.

Applications are invited from registered medical practitioners (male) for the post of Senior Assistant Resident Medical Officer at the Tuberculosis Sanatorium, Killingbeck (242 beds).

Applicants must be unmarried, and preference will be given to those who have held a general hospital appointment and had experience in the treatment of pulmonary and surgical tuberculosis in sanatoria. Under the present salaries scale of the Council, the commencing salary for the post is £425 per annum and the maximum salary £500 per annum, with board, residence and laundry. These emoluments being valued for superannuation purposes at £120 per annum, together with annual increments of £25 subject to satisfactory service. The first increment will take effect on April 1st following the completion of twelve months' service.

The person appointed will be required to pass a medical examination and to contribute to the Superannuation Fund established under the Local Government and Other Officers' Superannuation Act, 1922.

Applications, on a form to be obtained from the undersigned, together with copies of three recent testimonials, and endorsed "Tuberculosis Officer," must be received at the Health Department, 12, Market Buildings, Vicar Lane, Leeds, 1, not later than 10 a.m. on Saturday, January 15th, 1938.

Canvassing in any form, either directly or indirectly, will be a disqualification.
J. JOHNSTONE JERVIS,
Medical Officer of Health.

LEICESTER ROYAL INFIRMARY. (500 Beds) RESIDENT ANAESTHETIST.

Applications are invited for the above post, for a period of six months in the first instance. Salary £150 per annum for the first six months, £200 per annum for the second six months, and £225 for the third six months, together with board, residence and laundry.

Applications, giving full particulars, accompanied by copies of three recent testimonials, should be forwarded to the undersigned forthwith.
GEO. W. COOLING,
January 8th, 1938. House Governor.

COUNTY BOROUGH OF HUDDERSFIELD ST. LUKE'S HOSPITAL. RESIDENT MEDICAL OFFICER.

Applications are invited from registered medical practitioners for above appointment, which is for one year. Salary £230 per annum, with board, residence and laundry.

Applications, stating age, training, qualifications and experience, should be forwarded to the Medical Officer of Health, Huddersfield, so as to reach him not later than January 15th, 1938.

Town Hall, Huddersfield, January, 1938. SAMUEL PROCTOR.
Town Clerk.

LIVERPOOL DENTAL HOSPITAL. Pembroke Place, 3.

The Committee invites applications for the post of HON. ANAESTHETIST. Attendance one half-day per week. Applicants must possess a medical qualification.

Further particulars may be obtained from the Hon. Director, by whom applications must be received not later than Wednesday, February 2nd, 1938.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE.

During 1938, the Secretary of State for the Colonies proposes to select a number of Medical Officers to fill vacancies, the majority of which will occur in Tropical Africa and Malaya.

QUALIFICATIONS.—Candidates must be British subjects of European parentage, under 35 years of age, and must possess a medical qualification registrable in the United Kingdom. Preference will be given to candidates who have held Hospital or Public Health appointments, or who have special knowledge of anaesthetics, radiology, surgery, medicine, ophthalmology, gynaecology and midwifery, diseases of the ear, nose and throat, venereal diseases, etc.

SALARY.—Initial salaries vary from £600 to £700, and rise by increments to a maximum of between £1,000 and £1,200.

PRIVATE PRACTICE.—Private practice is not allowed as of right, but in the case of some appointments it is permitted on certain conditions.

QUARTERS.—In Tropical Africa, free quarters, or an allowance in lieu, are provided. In Malaya, quarters are provided at an annual rental not exceeding 6% of the officer's salary.

PASSAGES.—Free first-class passages are provided on first appointment and when proceeding on and returning from leave. Assistance is also given towards family passages.

TERMS OF APPOINTMENT.—The appointments are pensionable, subject to a probationary period which varies from two to three years.

COURSES OF INSTRUCTION IN TROPICAL MEDICINE AND HYGIENE.—Selected candidates will normally be required to attend a course of instruction leading to the Diploma in Tropical Medicine and Hygiene before proceeding overseas.

DUTIES.—Although Medical Officers are appointed in the first instance for general service, there are opportunities for work in special branches of medicine and surgery, in public health, and in medical research.

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 2, Richmond Terrace, Whitehall, London, S.W.1.

HIS MAJESTY'S COLONIAL SERVICE

COLONIAL MEDICAL SERVICE.

A vacancy exists for an ASSISTANT MEDICAL SUPERINTENDENT at the CENTRAL MENTAL HOSPITAL, TANJONG RAMBUTAN, in the FEDERATED MALAY STATES.

Qualifications.—Candidates must be British Subjects of European parentage, under 35 years of age, and must have had at least two years' experience as an Assistant Medical Officer in a County, City or Borough Mental Hospital, in Great Britain or Ireland. Possession of medical qualifications registrable in the United Kingdom and a Diploma in Psychological Medicine is essential.

Salary.—£840 a year rising by annual increments of £35 to £1,120 a year.

Quarters.—Furnished quarters are provided at a small rental.

Passages.—Free passages will be provided both for an officer and his family on first appointment and when proceeding on or returning from leave.

Terms of Appointment.—The appointment is pensionable, subject to a probationary period of three years in the first instance.

Duties.—The officer will be required to assist the Medical Superintendent in the treatment of patients, maintenance of discipline, etc., in the Mental Hospital. He may be required to give lectures and clinical teaching on mental diseases to students of the College of Medicine, Singapore.

Further particulars and forms of application may be obtained from the Director of Recruitment (Colonial Service), 2, Richmond Terrace, Whitehall, London, S.W.1.

ROYAL HOSPITAL, RICHMOND, SURREY.

Applications are invited for the following post, which falls vacant immediately:—
JUNIOR HOUSE SURGEON. £100 per annum, with board, furnished apartments and laundry. Candidates must be fully qualified, registered, and single. Form of application can be obtained from the Secretary-Superintendent.

GOVERNMENT OF INDIA

1. Applications are invited from women candidates for the appointment of PROFESSOR OF MATERNITY AND CHILD WELFARE at the ALL-INDIA INSTITUTE OF HYGIENE AND PUBLIC HEALTH, Calcutta.

2. Candidates must possess a registrable medical qualification and must have experience of the executive and administrative aspects of Maternity and Child Welfare. Preference will be given to candidates possessing also experience in directing or conducting research and in lecturing to students.

3. Agreement for five years in the first instance. Pay according to age and qualifications in scale Rs. 450, rising by triennial increments of Rs. 50 to Rs. 850 a calendar month, plus Overseas Pay of Rs. 100 when salary is Rs. 600 or less, or of Rs. 150 when salary is Rs. 650 or more. (Rupee = 1s. 6d. approximately). House allowance. Provision for 6d. approximate passage to India and return. Fund first-class termination of service (overseas pay and return passage admissible only to seaport and non-Asiatic domicile).
4. Further particulars and forms of application may be obtained, on application by postcard, from the High Commissioner for India, General Department, India House, Aldwych, London, W.C.2. Last date for receipt of completed applications January 17th, 1938.

ROYAL AIR FORCE DENTAL BRANCH

TEMPORARY CIVILIAN APPOINTMENTS

Vacancies exist at certain Royal Air Force Stations for temporary appointments as whole-time civilian dental surgeons. Preference will be given to applicants under 30 years of age.

Further information may be obtained by applying to the Secretary, Air Ministry (D.M.S.), Admiralty House, Kingsway, W.C.2.

ADDENBROOKE'S HOSPITAL, CAMBRIDGE.

The General Committee will, at their meeting to be held on January 25th, 1938, proceed to the election of an HONORARY DENTAL SURGEON. Applications, stating age, qualifications, etc., should be sent to the undersigned on or before January 18th, 1938.

I. A. BEARDSALL,
Secretary-Superintendent

ST. ANDREW'S HOSPITAL FOR MENTAL DISEASES FOR THE UPPER AND MIDDLE CLASSES, NORTHAMPTON.

A RESIDENT MEDICAL SUPERINTENDENT is required for this Institution. He must be either a Doctor of Medicine of one of the Universities of the United Kingdom or Ireland where residence and exercise are required to take a degree, or a Fellow or Member or Licentiate of one of the Royal Colleges of Physicians or Surgeons of the United Kingdom or Ireland, and must have had experience in the treatment of Mental Diseases. Salary £2,000 per annum, with unfurnished residence, coals, electric light, vegetables, and washer allowance. Further increments will be at the discretion of the Committee of Management. The creation of the Committee of Management will be subject to a salary and emoluments will be subject to a deduction towards the Hospital's Superannuation Fund.

Candidates qualified as above are requested to send in their applications and not more than three testimonials on or before January 31st, 1938, to the Chairman, Sir Charles V. Gunning, Bart., C.B., C.M.G., c/o The Clerk of the Committee of Management, St. Andrew's Hospital, Northampton. Candidates whose qualifications are approved will be invited to attend a meeting of the Governors of the Hospital of which they will receive notice, and the testimonials of other candidates will be returned. The gentleman selected will be required to enter upon his duties not later than May 2nd, 1938. Canvassing is strictly prohibited, and disqualify.

By Order of the Committee of Management,
CHARLES V. GUNNING,
Chairman

UNIVERSITY OF WALES THE WELSH NATIONAL SCHOOL OF MEDICINE.

Applications are invited for the DAVID DAVIES PROFESSORSHIP OF TUBERCULOSIS. The person appointed will also hold office as Director of Research and Honorary Consultant to the Welsh National Memorial Association. The appointment is a full-time one, and the combined emolument is at the rate of £1,500 per annum. Further particulars of the appointment may be obtained from the Secretary, The Welsh National School of Medicine, The Parade, Cardiff.

S. C. EDWARDS,
Secretary

COUNTY BOROUGH OF BIRKENHEAD.
Department of the Medical Officer of Health.

BIRKENHEAD MUNICIPAL HOSPITAL.
DEPUTY MEDICAL SUPERINTENDENT.

Applications are invited for the appointment of Deputy Medical Superintendent (Resident) at the Birkenhead Municipal Hospital (547 beds). The remuneration attached to the appointment will be £450 per annum, rising by increments of £25 to a maximum of £550 per annum, together with residence, board, etc.

Applicants must be single, fully qualified and registered, and must be capable of performing major surgical operations.

The appointed candidate will have the status of Assistant Medical Officer on the staff of the Medical Officer of Health.

The appointment will be made subject to the Local Government and Other Officers' Superannuation Act, 1922, and is determinable by three months' calendar notice on either side.

Candidates who possess an extra qualification in surgery will be specially considered.

Forms of application and further particulars relating to this appointment can be obtained from Dr. MORLEY MATTHEWS, Medical Officer of Health, 9, Hamilton Square, Birkenhead.

Canvassing, directly or indirectly, will disqualify the applicant.

Applications, endorsed "Deputy Medical Superintendent," should reach the undersigned not later than Saturday, January 15th, 1938.

Town Hall, E. W. TAME, Town Clerk.

DERBYSHIRE COUNTY COUNCIL.
WALTON SANATORIUM, Near Chesterfield.

JUNIOR RESIDENT ASSISTANT MEDICAL OFFICER (Male).

Applications are invited for the post of Junior Resident Assistant Medical Officer at the Derbyshire County Sanatorium. Candidates with previous institutional experience of tuberculosis will be preferred, and practical experience of artificial pneumothorax work will be considered an additional qualification. Candidates must be single.

Salary at the rate of £350 per annum, rising by annual increments of £25 to £450 per annum, together with board, lodging, etc.

The successful candidate will devote the whole of his time to the duties of the Office.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the person appointed will be required to pass a medical examination.

Application forms may be obtained from the undersigned, to whom they must be returned, together with copies of not more than three recent testimonials, on or before January 20th, 1938.

W. M. ASH, County Medical Officer.

New County Offices, County Medical Officer, Derby.

January 3rd, 1938

COUNTY MENTAL HOSPITAL.
Whittingham, Preston, Lancs.

RESIDENT JUNIOR ASSISTANT MEDICAL OFFICER, single, required. Salary £500, rising by increments of £25 to £600. No emoluments. £50 per annum is paid when the successful candidate obtains the Diploma in Psychological Medicine. The successful candidate will be required to live in the hospital and charges at the rate of £150 per annum will be made for board, fuel, and apartments and washing. Candidates must be duly registered under the Medical Act.

Applications, stating age, which must not exceed 30, qualifications and copies of testimonials, should reach the Medical Superintendent not later than the morning of January 18th, 1938. The successful candidate will be required to undergo medical examination. The appointment is subject to the provisions of the Asylums Officers' Superannuation Act, 1909, and the Regulations of the Lancashire Mental Hospitals Board.

KENT COUNTY COUNCIL.
RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the post of Resident Assistant Medical Officer at the County Hospital, Pembury (520 beds).

The salary for the appointment is £250 a year, with residential emoluments which are valued at £120 a year.

The appointment is a whole-time one, and will be for a period of one year only and not renewable.

Forms of application can be obtained from the Public Assistance Officer, Tonbridge Road, Maidstone, to whom applications must be sent by 10 a.m. on Monday, January 25th, 1938.

Sevenson House, W. L. PLATTIS, Clerk of the County Council, December 24th, 1937.

COUNTY BOROUGH OF WEST BROMWICH.

HALLAM HOSPITAL (472 beds).

HOUSE PHYSICIAN.

Applications are invited from duly qualified Male Registered Practitioners for the above-mentioned post.

The appointment is for six months, with eligibility for a further six months. Either party may give six weeks' notice terminating the appointment. There is a visiting staff of eight physicians and surgeons, one resident surgical officer and three resident medical officers.

The person appointed will be required to act under the general direction of the Medical Officer of Health and the Medical Clinical Superintendent.

Salary £200 per annum, and board residence. All fees received by the person appointed will be payable into the funds of the Council.

Applications, stating age, experience and qualifications, together with copies of three recent testimonials, must be forwarded to the Medical Officer of Health, 2, Lodge Road, West Bromwich, so as to arrive not later than by first post on Thursday, January 13th, 1938.

Town Hall, ALFRED WICKHAM, Town Clerk.
West Bromwich, December 24th, 1937.

BUXTON CLINIC FOR RHEUMATISM AND ALLIED DISEASES.

Applications are invited for the appointment of HOUSE PHYSICIAN. Candidates must be fully qualified and registered, and must have had previous hospital experience. The appointment is for six months, but is renewable.

Applications, accompanied by three recent testimonials, should be in the Secretary's hands not later than January 22nd, 1938.

The appointment is to start on February 1st, 1938. The Clinic has full facilities for physical and hydrological treatment, and has its own radiological department. Investigatory work in Biochemistry, Pathology, and Bacteriology is carried on in conjunction with the Devonshire Royal Hospital.

Salary: £150-£200 per annum, with board, residence and laundry.

Buxton, H. S. NEEDHAM, Secretary, Buxton Clinic, Ltd.

ANCOATS HOSPITAL, MANCHESTER.

ASSISTANT PATHOLOGIST, lady or gentleman, whole-time appointment, no private work allowed. Salary £400 per annum: live out. Luncheon and tea provided. The appointment is for twelve months and is renewable. During the first six months a certain amount of research work will be conducted.

RADIOLOGICAL OFFICER, lady or gentleman, whole-time appointment, non-resident, no private work allowed. Salary £400 per annum, with luncheon and tea. The appointment is for twelve months and is renewable. Candidates must hold the D.M.R.E. diploma.

Applications for the above posts, stating age and particulars of qualifications and experience, to be forwarded to the undersigned on or before January 19th, 1938, together with copies of three recent testimonials.

By Order of the Board,
HERBERT J. GAFFORNE,
General Supt. and Secretary.

BOOTLE GENERAL HOSPITAL.
BOOTLE, LIVERPOOL, 20. (103 Beds.)

ONE HOUSE PHYSICIAN.

TWO HOUSE SURGEONS.

ONE CASUALTY OFFICER.

Applications are invited for the above posts, tenable for 6 months from April 1st next. The salary attached to each post is £120 per annum with board, residence and laundry.

Applicants must be duly qualified and registered under the Medical Act.

Applications, with copies of testimonials, should reach me as soon as possible.

A. J. COOPER,
Secretary-Superintendent.

HOVE GENERAL HOSPITAL.
(50 Beds.)

Applications are invited for the posts of HONORARY CLINICAL ASSISTANTS in the Gynaecological Department and in the Ear, Nose and Throat Department. Typewritten applications showing qualifications and past and present appointments must be received by the undersigned not later than February 1st, 1938. No testimonials need be sent in the first instance.

K. C. BOOKER,
Secretary-Superintendent.

CITY MENTAL HOSPITAL, HUMBERSTONE, LEICESTER.

ASSISTANT MEDICAL OFFICER (Male).

Residential General Hospital experience is desirable. Salary £150 per annum, together with board, lodging, washing and attendance, valued for purposes of superannuation at £150 per annum. If the applicant be married he will be permitted to live out, and the salary will commence at £200 rising by £50 per annum to £600. An additional £50 per annum will be paid for possession of a D.P.M.

The appointment is subject to the provision of the Asylums Officers' Superannuation Act, 1909.

There is a good laboratory and two active Psychiatric Clinics, one attached to the Leicester Royal Infirmary.

Applications, giving particulars of experience, etc., together with names of three referees—one of which should be non-professional and marked "A.M.O." to be sent to the Medical Superintendent.

KENT AND SUSSEX HOSPITAL.

(a) SENIOR HOUSE SURGEON (Male).
(b) JUNIOR HOUSE SURGEON (Male).

Remuneration at the rate of £200 and £150 per annum respectively, with board, residence, etc.

Candidates must be fully qualified and registered, and previous Hospital appointment experience is desirable. Duties to commence February 1st, 1938.

The successful candidates will be appointed for six months, and may apply for re-election.

Applications, stating age, qualifications, experience, and not more than three recent testimonials, to be forwarded to the undersigned immediately.

H. B. COATES,
January 4th, 1938. Secretary-Superintendent.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.
(114 Beds.)

Applications are invited from duly qualified Medical Practitioners for the post of HOUSE SURGEON at the above Hospital.

Salary £150 per annum (rising to £150 at the end of six months) satisfactory service, and £10 laundry allowance.

The Resident Staff consists of a Resident Surgical Officer and three House Surgeons.

Applications, with testimonials and evidence of registration, must be received not later than Thursday, January 6th, 1938.

J. W. PEARCE,
General Superintendent.

BEDFORD COUNTY HOSPITAL.

Wanted, an HONORARY PATHOLOGIST for Bedford County Hospital. Facilities given for private work. Applications to be sent to the Secretary.

(AMENDED ADVERTISEMENT.)
MIDDLESBROUGH EDUCATION COMMITTEE.
 Appointment of ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly qualified candidates, who are not over 45 years of age, for a position as Assistant School Medical Officer to act under the School Medical Officer in connection with the medical inspection and treatment of school children, and such other duties as may be required by the Education Committee.

Commencing salary £500 per annum (provided the successful candidate has had not less than three years' postgraduate experience), rising by annual increments of £25 to £700 per annum. The Committee may, at their discretion, take into account previous experience as an Assistant School Medical Officer in determining the amount of the commencing salary. The successful candidate will be required to devote his (her) whole time to the duties of the office. The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the successful candidate will be required to pass satisfactorily a medical examination. The appointment will be terminable by two calendar months' notice on either side.

Forms of application may be obtained on application to the Director of Education, Education Offices, Woodlands Road, Middlesbrough, to whom completed forms should be returned not later than Monday, January 17th, 1938.

Canvassing in any form will disqualify.
 Town Clerk's Office, - PRESTON KITCHEN.
 Municipal Buildings, Town Clerk.
 Middlesbrough.
 December 31st, 1937

CITY OF BIRMINGHAM EDUCATION COMMITTEE

Appointment of ASSISTANT SCHOOL MEDICAL OFFICER (male or female).

Candidates must have had at least three years' experience in the practice of their profession subsequent to obtaining a registrable qualification. Salary according to "Askwith" Scale (£500 to £700 by annual increments of £25). £10 per annum travelling expenses allowed.

Forms of application (to be returned not later than first post on Monday, January 31st, 1938), together with further information, may be obtained from the undersigned on receipt of a stamped addressed foolscap envelope. Communications should be endorsed "Assistant School Medical Officer." Canvassing will disqualify.

Education Office, P. D. INNES, Chief Education Officer.
 Margaret Street, Birmingham, 3.
 January 1st, 1938.

LANCASHIRE COUNTY COUNCIL.
HIGH CARLEY SANATORIUM, near Uxterston.
JUNIOR ASSISTANT MEDICAL OFFICER.

Applications are invited for the post of Junior Assistant Medical Officer (male, unmarried) for the High Carley Sanatorium, near Uxterston, which contains 130 beds for adult cases of pulmonary tuberculosis, and 21 beds in the Oubas House Children's Sanatorium, near Uxterston, for pulmonary cases. Salary £300 per annum, together with board, residence and laundry.

The appointment will be for a period of twelve months. The medical staff consists of medical superintendent and one assistant. Mr. Morrison Davies acts as senior Visiting Consulting Chest Surgeon. There are excellent facilities for reading for M.D. Forms of application and conditions of appointment obtainable from Central Tuberculosis Officer, County Offices, Preston. Letters to be marked "High Carley M.O."

Closing date January 24th, 1938.
 GEORGE ETHERTON,
 County Offices, Clerk of the County Council.
 Preston, January 4th, 1938.

CITY AND COUNTY OF BRISTOL.
SOUTHMEAD MUNICIPAL GENERAL HOSPITAL.
JUNIOR ASSISTANT RESIDENT MEDICAL OFFICER.

Applications are invited for the above appointment which is tenable for six months at a salary of £200 per annum.

Applications, accompanied by three recent testimonials, to be sent to the Medical Officer of Health, 40, Prince Street, Bristol, 1, forthwith.

BOROUGH OF EALING.
ASSISTANT MEDICAL OFFICER OF HEALTH.
RESIDENT ASSISTANT MEDICAL OFFICER.

Applications are invited for the above appointments from duly qualified medical men with a Public Health qualification.

Assistant Medical Officer (Man).—A candidate must have had at least three years' experience in the practice of his profession. The person appointed will be required to carry out medical inspection of school children and child welfare work and perform such other duties as may be allotted as Assistant to the Medical Officer of Health and School Medical Officer.

He will be required to devote his whole time to the duties, and will not be allowed to engage in private practice. The salary will be at the rate of £600 per annum, rising by £25 per annum to £700.

Resident Assistant Medical Officer. (Man—Single).—A candidate must have had experience in the treatment of cases of infectious disease at an Isolation Hospital. The duties will include the medical care of patients in the Chiswick and Ealing Isolation Hospital, South Ealing, and the medical inspection and treatment of school children at schools and health centres in the borough of Ealing.

The person appointed will reside at the Isolation Hospital where furnished rooms and board will be provided.

He will be required to devote his whole time to the duties and will not be allowed to engage in private practice. The salary will be at the rate of £350 per annum, rising by £25 per annum to a maximum of £550, plus board and residence as indicated above and valued at £150 per annum.

A deduction of 5 per cent. will be made from the salary in each case in accordance with the provisions of the Local Government and Other Officers' Superannuation Act, 1922, which has been adopted by the Council, and the appointment will be subject to passing the Council's medical examination in connection therewith. Canvassing will be a disqualification.

Copies of the application forms and terms of appointments can be obtained from Dr. Thomas Orr, Medical Officer of Health, Town Hall, Ealing, W.5, to whom applications accompanied by copies of not more than three recent testimonials must be delivered not later than January 20th.

R. H. WANKLYN,
 Town Hall, Ealing, W.5. Town Clerk.

BOROUGH OF EALING.
OPHTHALMIC SURGEON.

Applications are invited from registered medical practitioners of recognised consultant and specialist status in ophthalmology for the position of Ophthalmic Surgeon in connection with the Council's Health Centres. The successful applicant will be required to attend on three sessions a week during 40 school weeks, or 120 sessions in the year, for the purpose of examining and advising patients referred to him by the medical staff of the School Medical and Maternity and Child Welfare Services.

The remuneration will be £275 per annum. Canvassing will be a disqualification.

Forms of application and copies of terms of appointment may be obtained from Dr. Thomas Orr, Medical Officer of Health, Town Hall, Ealing, W.5, to whom applications, accompanied by three recent testimonials and endorsed "Appointment of Ophthalmic Surgeon," must be delivered not later than January 20th.

R. H. WANKLYN,
 Town Hall, Ealing, W.5. Town Clerk.

COUNTY BOROUGH OF BLACKBURN.
LADY ASSISTANT MEDICAL OFFICER OF HEALTH AND ASSISTANT SCHOOL MEDICAL OFFICER.

Applications are invited from duly registered women practitioners for the appointment of Assistant Medical Officer of Health and Assistant School Medical Officer to act under the direction and supervision of the Medical Officer of Health who is also School Medical Officer. The salary is at the rate of £600 per annum, rising by annual increments of £25 to £700 per annum.

The person appointed must, prior to April 1st, 1930, have held the appointment of Medical Officer of an Ante-Natal Clinic with the approval of the Minister, or have had at least three years' post-graduate experience in the practice of her profession and special experience of practical midwifery and ante-natal work.

Preference will be given to candidates who have enjoyed special postgraduate experience in the treatment of venereal diseases, and of diseases of children, and who hold a registrable degree or diploma in Public Health.

Applications to be made on forms to be obtained from the Medical Officer of Health, Victoria Street, Blackburn, and returned to him not later than January 22nd, 1938, endorsed "Assistant Medical Officer of Health."

CHAS. S. ROBINSON,
 Town Hall, Blackburn. Town Clerk.
 December 17th, 1937.

CITY AND ROYAL BURGH OF DUNFERMLINE.
RESIDENT OBSTETRICAL OFFICER.

Applications are invited for the post of Resident Obstetrical Officer (male) at the Maternity Hospital (35 Beds), Dunfermline.

Candidates should have held previous resident appointments in a Maternity Hospital and have had experience in ante-natal and post-natal work. Preference will be given to candidates who hold or are reading for membership of the College of Obstetricians and Gynaecologists. The officer appointed will be called on to act as outdoor consultant under the Maternity Services (Scotland) Act, 1937, and will also be required to assist in the Maternity and Child Welfare Scheme and to undertake such other duties as may be assigned to him by the Medical Officer of Health.

The salary will be at the rate of £400 per annum rising by annual increments of £25 to £475 per annum with emoluments valued at £150 per annum and travelling expenses.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922, and the selected candidate will be required to pass a medical examination. The appointment will be terminable by three months' notice on either side.

Forms of application may be obtained from Dr. C. Barclay Reekie, Medical Officer of Health, 1, Douglas Street, Dunfermline, and must be returned to him, accompanied by copies of three recent testimonials, not later than January 15th, 1938. Canvassing will disqualify.

ANDREW SHEARER,
 City Chambers, Dunfermline. Town Clerk.
 December 20th, 1937.

CITY OF LEEDS
ASSISTANT MEDICAL OFFICER.

Applications are invited from qualified and registered medical practitioners for the post of Assistant Medical Officer for Maternity and Child Welfare. Applicants must have had not less than three years' postgraduate experience, including experience in General Medicine and Surgery, and special experience in Obstetrics and Ante-Natal work, and in the treatment of Children's Diseases and Disease of Women. Preference will be given to candidates possessing the D.P.H.

Under the present Grading Scheme of the Council, the commencing salary for the post is £500 per annum and the maximum salary £700, with annual increments of £25, subject to satisfactory service, and the first increment will take effect on April 1st following the completion of twelve months' service.

The person appointed will be required to pass a medical examination, and to contribute to the Superannuation Fund established under the Local Government and Other Officers' Superannuation Act, 1922. The appointment will be terminable by one month's notice on either side.

Form of application and particulars as to the duties of the appointment may be obtained from the undersigned.

Applications, endorsed "Maternity and Child Welfare Officer," together with copies of three recent testimonials, must be delivered at the Health Department, 12, Market Buildings, Vicar Lane, Leeds 1, not later than 10.30 a.m. on Saturday, January 22nd, 1938.

Canvassing in any form, either directly or indirectly, will be a disqualification.

J. JOHNSTONE JERVIS,
 Medical Officer of Health

DAGENHAM URBAN DISTRICT COUNCIL.**ASSISTANT MEDICAL OFFICER OF HEALTH (Male).**

Applications are invited from duly qualified medical men, having at least two years' experience in a comparable position, for the post of Assistant Medical Officer of Health. Preference will be given to candidates possessing the Diploma in Public Health, or an equivalent qualification. Commencing salary £500 per annum, rising by annual increments of £25 to £700, subject to Superannuation deductions.

The person appointed will be required to devote the whole of his time to the duties of the office, which consists mainly of work in the Maternity and Child Welfare Department, but may also include duty in any section of the health services of the district.

Experience in ante-natal and maternity and child welfare work is essential.

Opportunities will be available for acquiring experience in Public Health administration. Applications, on forms obtainable from the Medical Officer of Health at the undermentioned address, should be returned to the undersigned on or before January 15th, 1938.

Canvassing disqualifies.

F. W. ALLEN,
Civic Centre, Dagenham, Essex
January 4th, 1938. Clerk of the Council.

Receipts for last year amounted to £1,176, including £492 from a Panel of about 1,150 patients. Suitable house available, freehold £900. Premium 1½ years' purchase.
15. **LANCS.**—Old-established PRACTICE available owing to ill-health of vendor. Receipts for last year £662, including Panel of about 620 patients. Freehold house with 2 reception, 3 bedrooms and 2 apts. There is stated to be good scope for increase as the receipts were formerly £1,200 p.a. Price for Practice and house £2,100.
16. **WEST OF ENGLAND**.—Good-class residential town.—A ONE-THIRD SHARE with increase up to one-half is offered in a better middle-class Practice at present averaging £1,200 p.a. Appointments worth about £350. Panel of 300 patients. Fees 5/- to 21/-. Flat available in vendor's house for single man. Rent £40 p.a., inclusive of rates.
17. **NORTH WALES**.—Good-class long-established PRACTICE in very attractive residential and seaside resort. Cash receipts for last 16 years over £1,200 every year. Panel 425. Good house with 2 small gardens to rent or purchase, freehold. Socially very pleasant. Premium £1,800. Vendor going abroad.
18. **HERTS**.—Country town on outskirts of London.—Very old-established PRACTICE held by vendor for 30 years. Gross cash receipts about £1,000 p.a., including Panel of 600 patients. Nice house with 2 reception, 4 bedrooms, good garden on rental. Premium 2 years' purchase.
19. **LEV. ANGLIA**.—Within reach of two good towns. Old-established unopposed PRACTICE averaging over £1,000 p.a., including Panel producing over £450 p.a. Low expenses. Detached house with 2 sitting and 5 bedrooms, etc. Rent £70 p.a. Premium £1,750.
20. **NORTH CORNWALL**.—Country PRACTICE in picturesque district near coast and within easy reach of two good towns. Stated to produce nearly £1,000 p.a., including Panel of £320.
21. **HANTS**.—Recently established PRACTICE in pleasant locality. Earnings for the first year about £230, with Panel of 80 and increasing. Stated to offer considerable scope for development. Very nice small house can be rented. Moderate premium for quick sale, as vendor wishes to take up another appointment.
22. **WITHIN 25 MILES OF LONDON—PARTNERSHIP**, with surgical scope. A one-fourth share, with increase later, is for disposal in an old-established Practice, producing about £4,800 p.a. Fees 3/6 to 21/-. A suitable house can be secured. Incoming partner must have a Fellowship, be experienced and not over 35 years of age. A prelim. assistantship is offered.
23. **LONDON, SOUTH-EAST—STEADILY INCREASING OUTLYING DISTRICT**.—Recently established PRACTICE rapidly growing and producing for last 12 months £1,387. Selected Panel of 350. Suitable house with 2 reception, 3 bedrooms, etc., garden, garage. Can be rented on lease. Premium £2,000.
24. **COAST TOWN**.—Old-established PRACTICE held by vendor for 3½ years, who now wishes to specialise. Gross receipts for last year approximately £2,183, including panel of 770 and appointments producing about £100 p.a. Visits from 5/-. Good house available, containing 2 reception, 7 bedrooms, Professional accommodation, etc. Freehold £1,100. Premium 2 years' purchase or near offer.
25. **MONMOUTHSHIRE**.—Middle-class PRACTICE, established over 20 years, producing for last twelve months £1,430, including panel of 300. Fees 3/6 to 21/-. Good house with 2 reception, 6 bedrooms, etc. Separate Professional rooms, garden and garage. Rent £125 p.a. Premium 1½ years' purchase.
26. **WEST COAST**.—Well-established PRACTICE, producing about £1,500 p.a., including panel of 1,450. Suitable house on rental at £50 p.a. Premium 1½ years' purchase.
27. **EASTERN COUNTIES**.—Mixed-class PRACTICE in pleasant agricultural district producing for last twelve months over £1,300 p.a. Fees 3/6 to 21/-. Nice house in good position with 2 reception, 4 bedrooms, dressing room, etc. Separate professional accommodation. Modern conveniences. Garden, garage. Price, freehold £1,300. Sport of all kinds and schools within reach. Prem £1,685.
28. **CROYDON AREA**.—Recently established PRACTICE. Receipts for last 12 months over £650, including panel of 350. House with 3 bedrooms, etc., garden and garage can be rented at £85 p.a. Reasonable premium for quick sale, owing to ill-health.
29. **EASTERN COUNTY MARKET TOWN—HALF-SHARE PARTNERSHIP** in Practice established about 100 years, producing for last 12 months Gross cash receipts £1,200 p.a., including panel of 1,000 patients. Panel and P.A.C. are young and have had hospital experience. Premium 2 years' purchase.
30. **SURGICAL PARTNERSHIP** in delightful district within easy reach of London. A fifth partner is required in an old-established Practice. There is little sitting done under 10/6, although the patients come from all classes. Incoming partner, who must hold the English Fellowship, would do all the surgery for the firm, but must be prepared to do general practice as well. Choice of houses.
31. **CROYDON AREA**.—Rapidly increasing PRACTICE producing about £1,800 p.a. Panel of about 1,100. Fees 1/6 to 3/-, with visits from 2/6 to 5/-. Practically all cash. Vendor specialising in midwifery. Suitable house available on rental. Premium £3,200.
32. **SUSSEX COUNTRY**.—Good NUCLEUS with scope for further increase. Receipts: 1935, £467; 1936, £625; 1937 for 7 months, £452. Panel produces about £267 included in above. Good house on rental.
33. **NORTH LONDON**.—Middle and better-class PRACTICE suitable for medical man with qualified wife or for working with a lady assistant. Gross cash receipts for last 12 months £1,681. Panel of 320, appointments worth about £70 p.a. Visits 5/- to 7/6. Good house with reception, 5 bedrooms, etc. Professional rooms, small garden, garage. Freehold for sale or might be rented. Premium 2 years' purchase or near offer.
34. **PARTNERSHIP—LONDON, EAST—A HALF-SHARE** of middle and working-class Practice, producing for immediate past 12 months £4,567 p.a. Panel of over 5,000. Suitable house can be obtained.
35. **NORTH-EAST COAST**.—Old-established PRACTICE, producing about £900 p.a., but stated to be capable of considerable increase. Choice of suitable houses. Partnership introduction will be given. Vendor retiring.
36. **WEST MIDLANDS—PLEASANT RESIDENTIAL TOWN—PRACTICE** producing about £1,600 p.a., including a selected Panel of about 560 patients. Mostly better-class and non-dispensing. Consultations 3/6 to 10/6. Visits 5/- to 1 guinea. Freehold house for disposal, contains 3 reception, 3 large and 3 smaller bedrooms with separate servants' quarters. Excellent consulting rooms, garage, etc. Premium £1,500.
37. **DEVON, SOUTH COAST**.—A well-established good-class entirely private PRACTICE producing for the past 12 months about £1,000. Panel could be had if desired. Fees 2/6, 3/6, 5/- and 7/6, with a few visits up to 21/-. Non-dispensing. Suitable house containing consulting room, 2 reception rooms, 6 bedrooms, for sale. Freehold £1,400. Partnership introduction. Would be suitable for ex-L.M.S. or similar.
38. **LONDON, E.C.2—LOCKUP PRACTICE** established 80 years for disposal. Income about £800-£900 p.a. with Panel of about 1,150 patients. Fees 2/6 and 3/6. Visits from 3/6. Suitable accommodation available consisting of consulting room, dispensary, waiting room, the remainder being sub-let for £280 p.a. Rent and rates £230 p.a. Premium 2 years' purchase to include about £50 fittings, fixtures, drugs, etc.
39. **COAST PRACTICE**.—Lock-up, 6 hours 10-1 and 5.30-6.30, producing about £1,000 p.a., including £200 from Panel and appointments. Suitable accommodation available.

ASSISTANTS REQUIRED.—1.—WEST OF ENGLAND. Large town. Outdoor with view to partnership. £300 p.a. all round. 2.—SOUTH-WEST COAST. Indoor, £300 p.a., with car allowance. 3.—NORTH LONDON. Indoor or outdoor, £350 p.a. all found. 4.—SOUTH-EAST. Indoor, £350 p.a. all found. 5.—SOUTHAMPTON. Outdoor, £300 p.a. all found. 6.—SURREY. Outdoor, £450. House or rooms available. 9.—HERTS. Indoor, £300 p.a. View to partnership.

The Agency has made arrangements for special facilities, on very favourable terms, to be afforded to approved purchasers for the advance of part of the premium for any suitable practice or partnership. Full details on application.

TRADE MARK 'WELLCOME' BRAND
CALCIUM MANDELATE COMPOUND

*An advance in the
 Mandelic Acid treatment
 of Urinary Infections*

'WELLCOME' CALCIUM MANDELATE COMPOUND has distinct advantages.

It is as effective therapeutically as sodium or ammonium mandelate without the marked nausea and digestive disturbances often associated with these salts.

Readily miscible in water.

Free from unpleasant flavour.

Ammonium chloride treatment not usually required.

A dose of one measureful is equivalent to 3 grammes of mandelic acid.

Amber-glass bottles containing 125 grammes. (Sufficient for a course of seven days' treatment.) Dose-measure and test papers in each carton.

Vitamin Concentrate or Natural Food?

The normal daily dosage of Bemax, i.e., $\frac{1}{2}$ -ounce, provides 200 International units of Vitamin B₁, which is from four to ten times as much as the recommended daily dosage of certain Vitamin B₁ "concentrates" advertised to the medical profession. If a higher intake is required, it is possible to supply as much as 600 to 800 units of Vitamin B₁ daily by the administration of three to four tablespoonfuls of Bemax, and this in an entirely natural form at only a fraction of the cost of concentrates.

The Vitamin B₁ potency of Bemax is assured by biological assay of every day's output, and is from 12-15 International Units per gramme, about 400 units per ounce.

BEMAX

A unique natural source of accessory nutritional factors.

Vitamin B₁—400 International Units
per ounce.—

Vitamin B₂—Flavin present
B₆—rich supply

Vitamin A—250 International Units (as Carotene).

Vitamin E—the richest natural source

Phosphorus—330 mg.

Magnesium— 99 mg. per ounce :

Iron — 3 mg. per ounce;

Copper — 0.45 mg.
per ounce

Complimentary carton sent on request.

The Bemax Laboratories,

(Dept. B. 51.), Upper Mall, London, W.6

Sterility and Habitual Abortion

The increasing use of Vitamin E for habitual abortion and sterility of dietary origin demands a wheat germ oil of proven high activity and of stable Vitamin value. Such an oil is available for the medical profession in Fertitol.

FERTILOL

Wheat Germ Oil Capsules

A highly active source of Vitamin E.

A complimentary box of Fertitol Capsules and brochure sent on request.

Vitamins Ltd.,

(Dept. B. 51.), Upper Mall, London, W.6.

**Benger's Food is specially devised
to be used with fresh cow's milk**

Benger's Food, when prepared, is a dainty food cream in which the tough curd of cow's milk has been broken down so that it can no longer form indigestible clots. Because it is so easy of assimilation Benger's Food is almost universally prescribed by the Medical Profession for enfeebled digestion, and for extreme conditions its prescription is almost standard. Benger's Food is so delicious that it is eaten with enjoyment by those who find milk, or diluted milk, unpalatable.

A Physician's sample and literature sent

CHURCHILL'S NEW BOOKS

MEDICAL BACTERIOLOGY

Descriptive and Applied. Including Elementary Helminthology

By L. E. H. WHITBY, C.V.O., M.D., F.R.C.P.

Third Edition. 79 Illustrations. 11s. 6d.

Thoroughly revised and brought up to date. Including a new chapter on theories of immunity.

Author with Dr. C. J. C. Britton of "Disorders of the Blood." Second Edition. 21s.

PRACTICAL PHYSIOLOGICAL CHEMISTRY

By PHILIP B. HAWK, M.S., Ph.D., and OLAF BERGEIM, M.S., Ph.D. With the aid of BERNARD L. OSER, Ph.D., and ARTHUR G. COLE, Ph.D.

Eleventh Edition. 7 Coloured Plates and 281 Text-figures. 35s.

For thirty years this volume has been a standard work, and the revised new edition will, it is felt, be as useful as its predecessors. A thorough revision has been made and much new matter incorporated.

THE SCIENCE AND PRACTICE OF SURGERY

By W. H. C. ROMANIS, M.B., F.R.C.S., and PHILIP H. MITCHNER, M.S., F.R.C.S.

Sixth Edition. 800 Illustrations. 2 Vols. 28s.

"This excellent textbook needs little recommendation. It has proved its worth, and has now held its place for many years as a guide to the student preparing both for qualifying and higher examinations."—THE LANCET.

MEDICINE

Essentials for Practitioners and Students

By G. E. BEAUMONT, D.M., F.R.C.P., D.P.H.

Third Edition. 74 Illustrations. 21s.

"... deals effectively with most of the subjects and problems likely to be encountered by medical students and practitioners."—THE PRACTITIONER

MEDICAL EMERGENCIES

By CHAS. NEWMAN, M.D., F.R.C.P.

Second Edition. 8s. 6d.

"... is full of sound medicine of the type which is not found in the standard textbooks. ... The book is able written and should be close at hand on the shelf in every practitioner's home."—THE MEDICAL PRESS

TEXTBOOK OF GYNAECOLOGY

By WILFRED SHAW, M.D., F.R.C.S., F.C.O.G.

Second Edition. 4 Coloured Plates and 253 Text-figures. 18s.

Thoroughly revised with new illustrations. Including a new chapter on Hormone Therapy.

THE MEDICAL DIRECTORY 1938

London, Provinces, Wales, Scotland, Ireland, Abroad, Navy, Army, and Air Force.

Ninety-fourth Annual Issue. 2,460 Pages. 59,858 Names. 36s.

This issue contains particulars of at least 30,000 changes.

"This book is one of the indispensable portions of the medical practitioner's equipment."—THE PRACTITIONER.

RECENT ADVANCES IN INDUSTRIAL HYGIENE AND MEDICINE

By T. M. LING, B.M., M.R.C.P.

29 Illustrations. 12s. 6d.

"... should prove of great value not only to students but also to practitioners. It contains a vast amount of information which is difficult to obtain from other medical textbooks, and therefore fills a very definite gap in medical literature. ... It can be said with confidence that this book will become an important reference volume and a worthy addition to the series."—THE MEDICAL PRESS AND CIRCULAR

RECENT ADVANCES IN THE STUDY OF RHEUMATISM

By F. J. POYNTON, M.D., F.R.C.P., and BERNARD SCHLESINGER, M.D., F.R.C.P.

Second Edition. 51 Illustrations. 15s.

"The book provides an excellent summary of the present knowledge of rheumatism."—THE GLASGOW MEDICAL JOURNAL

MODERN PSYCHOLOGY IN PRACTICE

By W. LINDESAY NEUSTATTER, M.B., M.R.C.P.

10s. 6d.

"This is a thoroughly practical textbook on the elementary aspects of applied psychology and the author's obvious wide experience, together with his sincerity, make it a commendable book which can be unreservedly recommended to all practitioners of medicine."—THE PRACTITIONER

EDEN AND HOLLAND'S MANUAL OF OBSTETRICS

By EARDLEY HOLLAND, M.D., F.R.C.P., F.R.C.S., F.C.O.G.

Eighth Edition. 12 Plates (5 Coloured) and 398 Text-figures. 24s.

The present edition has been more thoroughly revised than any other. There has been much rearrangement and many sections have been entirely rewritten. A large number of new illustrations have been inserted.

CHEMICAL METHODS IN CLINICAL MEDICINE

By G. A. HARRISON, M.D., B.Ch., M.R.C.S., L.R.C.P.

Second Edition. 3 Coloured Plates and 86 Text-figures. 21s.

"The importance of chemical tests and methods in clinical medicine is greater to-day than ever it was, and this book presents the subject in a manner that makes it indispensable to the progressive clinician."—THE PRESCRIBER

ANTENATAL AND POSTNATAL CARE

By F. J. BROWNE, M.D., F.R.C.S.E., F.C.O.G.

Second Edition. 79 Illustrations. 18s.

"It would be difficult to improve upon this book, since it covers the ground of its title so well and thoroughly. ... can be commended to every class of reader."—THE MEDICAL PRESS

APPLIED PHARMACOLOGY

By A. J. CLARK, M.C., M.D., F.R.C.P., F.R.S.

Sixth Edition. 83 Illustrations. 18s.

"It summarises in a masterly way the most recent available knowledge on the subject of all the useful drugs which remain, as it has been for fourteen years, the most useful book on the action and use of drugs written in the English language."—THE IRISH JOURNAL OF MEDICAL SCIENCE

THE TRUTH ABOUT VIVISECTION

By Sir LEONARD ROGERS, K.C.S.I., LL.D., M.D., F.R.C.P., F.R.C.S., F.R.S.

9 Illustrations. 5s.

"This excellent little book can be commended not only to the general public, but also to medical men, many of whom will for should wish to be informed of the present position of vivisection."—THE LANCET.

Mr. THERM (of Harley St.) says:

'Gas fires keep you warm, but leave the air cool and fresh!'

The ideal fire would be one which had no effect on the air which surrounded you, but warmed your body through and through (in much the way that the sun does in winter in Switzerland). A modern gas fire comes near that ideal, because it warms very largely by radiation. It emits an unusually large proportion of the shorter infra-red rays — the rays that are so beneficial because they penetrate without scorching. A modern gas fire projects a comforting glow of warmth through the room, yet never overheats or dries the air. And, of course, it keeps the air always on the move — actually changing the air in a room three or four times every hour.

GAS for healthy heat

ISSUED BY THE BRITISH COMMERCIAL GAS ASSOCIATION

FAMOUS TEXTBOOKS

Published by Saunders

"MACCALLUM"

Textbook of Pathology

"Since its original appearance in 1916, this well-known text-book has been re-published in a fresh edition at unvarying intervals of four years, a fact which itself indicates the sustained popularity of the work . . . the whole work is comprehensive, up to date, and easily readable. The illustrations are profuse."

—BRITISH MEDICAL JOURNAL

SIXTH EDITION

By W. G. MACCALLUM, M.D., Professor of Pathology and Bacteriology, Johns Hopkins University. Octavo of 1277 pages. 697 Original Illustrations, many in colours.

Cloth, 42s. net.

"HARROW & SHERWIN"

Textbook of Biochemistry

"The whole book is an example of what excellent results may be achieved by the collaboration of English-speaking workers of two nations . . . In this instance the editors must have begun the task with a clear notion of exactly what they were trying to do, and it can be honestly said that they have succeeded in doing it."

BY 31 TEACHERS

Edited by BENJAMIN HARROW, Ph.D., Associate Professor of Chemistry, The City College, College of the City of New York; and CARL P. SHERWIN, M.D., Sc.D., Dr.P.H., LL.D., Member of the Staff of St. Vincent's and French Hospitals, New York. Octavo of 797 pages. Illustrated.

Cloth, 25s. net.

"RANSON"

Anatomy of Nervous System

" . . . this text-book has proved its worth and acquired the popularity with teachers and students which it rightly deserves . . . The value of the book for the clinical student is that it is written from the standpoint of development and function by one well fitted to do so."

FIFTH EDITION

By STEPHEN W. RANSON, M.D., Professor of Neurology, Northwestern University Medical School. Octavo of 501 pages. 381 Illustrations, some in colours.

Cloth, 27s 6d. net.

"HOWELL"

Textbook of Physiology

"One of the main features of the book is its convenient size; no part of the subject is neglected, and the balance has been maintained with skill. The style is straightforward and the exposition clear . . . contains practically all the student requires in a small compass, and avoids many of the usual defects of a short book."

—LANCET

THIRTEENTH EDITION

By WILLIAM H. HOWELL, Ph.D., M.D., Emeritus Professor of Physiology, Johns Hopkins University. Octavo of 1150 pages. 308 Illustrations, many in colours. Cloth, 39s. net.

"MAXIMOW & BLOOM"

Textbook of Histology

"Of recent text-books on histology, this work, initiated by the late Prof. Maximow and completed by his colleague Prof. Bloom, is by far the most stimulating and instructive, and it is not surprising that there should be a demand for a second edition within three years of its appearance. The book has been thoroughly revised."

—THE LANCET

SECOND EDITION

By ALEXANDER A. MAXIMOW and WILLIAM BLOOM, Associate Professor of Anatomy, University of Chicago. Octavo of 662 pages. 530 Illustrations, some in colours.

Cloth, 30s. net.

"AREY"

Developmental Anatomy

" . . . a very complete account of the science of embryology . . . To students of medicine human embryology is of chief interest, and as information upon it is not available in reasonable detail, the author has made it the basis of his work."

THIRD EDITION

By LESLIE B. AREY, Ph.D., Professor of Anatomy, Northwestern University. Octavo of 593 pages with 1188 Illustrations on 547 figures, many in colours.

Cloth, 27s 6d. net.

The Modern Shorts for the sedentary man

The new, close-fitting Linia Shorts are a boon to the man leading a sedentary life. Made of elastic tricot, they exert a gentle, beneficial massage on the abdominal area, and give firm support. They are designed for wear instead of ordinary under-pants, and are light, easily laundered, porous and hygienic.

A development of Linia Shorts is Linia Reinforced Shorts which have a panel of firmer elastic over the abdomen for better support and control where there is a tendency to obesity.

You can order by post

Perfect fitting guaranteed or money refunded. We make a reduction of 2s. in the £ on purchases for personal use to members of the Medical Profession.

May we send you a fully explanatory booklet?

Prices

Linia Shorts: Popular Model, 25/-; De Luxe Model, 30/-; Standard Model, 17/6.

Nujol Laboratories confidently commend this new and efficient medicament . . .

Stemcol for cough

The Stemcol formula contains nothing revolutionary. It embodies expectorants, demulcents and antiseptics long approved by the medical profession. What is new, however, in Stemcol is the combination of these essential medicaments with Nujol . . . the standard viscosity liquid paraffin . . . in a pleasantly flavoured intimate emulsion. Stemcol contains no narcotics or sedatives and can, therefore, be prescribed for quite young children and the aged tracheitic or bronchitic patient with full confidence in its efficiency and safety. Stemcol has been the subject of a large number of favourable reports in:

PHARYNGEAL COUGH

The Prescription of **DEAF AIDS** through the **AMPLIVOX** **AUDICLE**

It is well known that it is desirable to match amplification curves of a deaf aid to the hearing loss which can in most cases be measured at the threshold intensity. Medical investigators have classed audiograms in three groups, and have thus indicated that the nearest practical approach to prescription at the present time is to have instruments with three different amplification curves, conforming to these characteristic audiograms. The **AMPLIVOX AUDICLE** (Model DT8) incorporates all three characteristics, and is therefore of great value in indicating if a deaf aid can be recommended in any particular case. The required characteristic can be incorporated in another instrument as selected by the user. Full particulars of the **AMPLIVOX AUDICLE** are given in a Research Bulletin which can be obtained on application from

The **AMPLIVOX** is obtainable in the United Kingdom only from the manufacturers—**AMPLIVOX LTD.**—and from Messrs. T. Hawksley, W. H. Pettifor, and Aids for the Deaf. There are appointed representatives in Australia, New Zealand, Canada, South Africa, India, the I.F.S., Northern Ireland, France, Holland, Norway, Sweden and Denmark.

the scientific contraceptive

MIL-SAN is submitted to members of the medical profession who are interested in the control of conception, in the firm belief that it is the most effective contraceptive produced in the light of present-day medical knowledge. Further that it is non-injurious, unobjectionable and hygienic in use and simple to apply.

A booklet and medical specimen pack are sent, on request, to members of the profession. Information regarding the basis of the formula, the ingredients, the tests made and the action and behaviour of the product are set out fully,

while the specimens sent demonstrate clearly the simplicity and advantages of the application method. There are no contra-indications to the use of MIL-SAN with a dependable condom or a properly fitted occlusive pessary. It is only by such combined use that the consequences of misuse of one or other of the methods can be minimized and the maximum practicable security obtained. MIL-SAN is on the N.B.C.A. Approved List for use with a cap or condom.

Please write name and address plainly or send card or note heading when requesting particulars and specimen tubes.

Modern Iron Therapy

Iron 'Jelloids' are an elegant and reliable means of administering the protocarbonate of iron. The preparation has none of the disadvantages of Pil. Bland. The iron content remains fresh and unoxidized indefinitely, and

injury to the teeth is avoided.

The 'Jelloids' are highly effective in the treatment of achlorhydric anaemia and indeed in all the simple anaemias in which massive iron therapy is indicated.

Iron Jelloids

You are cordially invited to apply for samples for clinical test.

OVALTINE

IN PREGNANCY

THE physiological drain of calcium, phosphorus, vitamins and other important food elements calls for replacement during pregnancy. Composed of milk, eggs and malt, 'Ovaltine' supplies these essentials in a delightful form which does not overtax the unstable maternal digestion. A cup of 'Ovaltine' on arising, during the early months, is often effective in controlling sickness and has a food value greater than three eggs.

IN LACTATION

To maintain lactation to the eighth month is an ideal not often realized under modern conditions of life. Ample evidence is available to show that 'Ovaltine' has a definite action in increasing the flow and enriching the quality of the milk. It has, moreover, a beneficial effect on the health of mother and child. The flavour is so agreeable that it can be taken for prolonged periods without any distaste arising.

A liberal supply for clinical trial sent free on request

LIVERPOOL and LONDON

FORMULA

Thyminic Acid	0.10
Hexamethylenetetramine	0.50
Anhydrous thylenecitrate	0.50
Hexamethylene Tetramine	0.25
Piperazine Tartrate	0.25
Lithium Carbonate	1.00
Sodium Benzoate	1.00
Lysine-cent Base	0.100

DIRECTIONS

One teaspoonful to be taken
morning and night in a
tumblerful of water.

Uralysol, in addition to being a solvent and eliminator of
pathological Uric Acid, is a powerful urinary antiseptic.

Normally there exists in the body a certain quantity of uric acid, which
assists general metabolism, and after it has played its part is eliminated together
with the normal thyminic acid of the organism. When, however, uric acid
is present in excess, the body needs additional thyminic acid to supplement the
resultant deficit of this normal solvent of uric acid.

Uralysol, by its thyminic acid content, supplies the agent
necessary to dissolve excessive uric acid.

The next step is the elimination of this thyminic-uric acid which, being
in excess of normal, necessitates treatment by an agent capable of enhancing
elimination.

Uralysol, by its content of hexamethylenetetramine and lysidin,
stimulates the organism to eliminate the pathological
uric acid already dissolved by its thyminic acid content.

Oral Vaccine for the prevention of Colds and Influenza

Since Genora brand Oral Vaccine was introduced to the Medical Profession last Winter, extensive clinical and laboratory tests have shown that it establishes a high degree of immunity against colds and influenza; the oral vaccine has also proved successful in the treatment of chronic bronchitis and similar respiratory infections.

This vaccine contains hemolytic streptococci, in addition to other organisms incriminated in the causation of coryza and influenzal infections. It has been found that the ingestion of the oral vaccine against colds and influenza also develops immunity to diseases caused by hemolytic streptococci.

Particulars concerning Genora brand Oral Vaccine will be found in the new brochure on Vaccine Therapy which has recently been published by Genatosan Ltd. This booklet also gives information regarding a wide range of vaccines administered by hypodermic injection and the standard types of Local Immunity Products. A copy of the brochure will gladly be supplied to any physician on request.

Nutritional Anaemia

In women, the incidence of anaemia is higher than in men because the physiologic demands for iron during menstruation and pregnancy are not satisfied by a diet which suffices for men. Iron must be added.

In Ovoiderrin, metallic iron is so combined with a protective protein colloid, as to constitute a most efficient and palatable haematinic.

Ovoiderrin does not irritate the mouth or stain the teeth, it does not constipate and is readily taken by children and by gravidæ with sensitive stomach and nerves.

It stimulates the jaded appetite and often induces intestinal peristalsis. In old age, Ovoiderrin acts as a stimulating general tonic.

The adult dose—a tablespoonful in milk or water, contains one grain of metallic iron in easily assimilable

OVOFERRIN

Brand Colloidal Iron Tonic

form; for children, the dose is two tea-spoonfuls. Ovoiderrin is prescribed in 11-ounce bottles. If you have not used Ovoiderrin in your practice, we shall be pleased to send you a trial bottle on request.

Reduced Mortality

In reviewing 19 cases of agranulocytosis seen at one New York City hospital during recent years, two observers comment on the reduction in mortality from 62% to 27% since the introduction of 'Pentnucleotide' (N.Y. State Jour. Med., 37:38, 1937). While giving due credit to the use of liver preparations and to transfusion, especially when the latter is given concurrently with 'Pentnucleotide,' the authors conclude: "'Pentnucleotide' appears to be the most effective form of treatment."

VEGETABLE PURÉES IN PEDIATRICS

A solution to the problem of home preparation

THE markedly improved nutrition and successful tolerance by infants to strained vegetables and fruits is rapidly securing a universal popularity for this dietary.

In theory there is no more desirable way of meeting systemic acidity, nutritional anaemia and supplying dietary bulk for intestinal residue in a non-irritant form.

In practice, however, defects in the home preparation of purées retard or defeat the end in view. The vegetables used are not fresh, overmuch water or boiling in uncovered kettles reduces the mineral and vitamin content, and coarse sieving allows harsh fibre to pass.

In consequence there is a growing demand on the part of physicians and mothers for such a product that shall have the highest possible nutritive value, and complete uniformity. Their attention having been drawn to this, the H. J. Heinz Company decided that here was a legitimate extension of their services in view of their wide buying resources and long-experience in the preparation of foods.

This company is accustomed to buying vegetables in those regions where they grow best, and to dealing with them within a few hours of their harvesting at the correct season of the

year. This last is, of course, highly important.

The best factory practice is inevitably better than home preparation, however careful. After scrupulous cleaning, for example, vegetables are cooked in the Heinz factories under light steam pressure with exclusion of air until just soft enough to be comminuted by extrusion and cutting. The whole process is so regulated that the juices of the vegetables are retained throughout, there are no mechanical losses of mineral salts, vitamins or other soluble nutrients, and the resulting purée is adjusted to the proper consistency for satisfactory marketing.

Before filling and sealing, the product is subjected to a process for the removal of any absorbed air, and sealing takes place *in vacuo*. Finally, the sealed containers are immediately sterilised under known conditions of time and temperature. By these means are secured the high nutritional qualities, uniformity and convenience that physician, mother and patient desire.

'PETROLAGAR'

When the muscular condition of the bowel has become flaccid or otherwise impaired, 'Petrolagar' is invaluable in restoring bowel responsiveness and regular bowel movement.

By supplying soft bulk, 'Petrolagar' brand paraffin emulsion affords more stimulation to the muscles, and the softness requires a smaller contraction wave to effect defæcation. Thus by providing the proper fæcal consistency the bowel can readily be re-educated to function in a regular daily manner.

COCAINE—With 1% cocaine solution, an average of 173 seconds elapse before the touch of a wooden applicator on the eye-ball is no longer felt.

BUTYN—With a 1% solution of Butyn, (Abbott), an average of only 68 seconds elapse before the touch of a wooden applicator is no longer felt.

COCAINE—With 1% cocaine solution the duration of anaesthesia is no longer than that obtained with 1% Butyn solution. Note the dilatation.

BUTYN—With 1% Butyn solution, anaesthesia persists for approximately as long as when 1% cocaine is used. Note absence of dilatation.

RAPID • DEEP • PROFOUND

Among local anaesthetics—including cocaine—which are effective on intact mucous surfaces, Butyn is unique in its ability to produce rapid, profound and prolonged anaesthesia. Butyn is widely used and is recommended for topical application in operative procedures on the eye, nose and throat, as well as for use in genito-urinary work. ● Butyn 2% Solution, the most widely used preparation of the drug, has proved to be as effective clinically as a 5% solution of cocaine. Used in the eye, Butyn does not affect the accommodation nor ocular tension. Neither does it cause drying of the conjunctiva as does cocaine. Two or three drops of the 2% Solution in the eye are sufficient for the removal of impacted foreign bodies or for the relief of pain due to abrasion of the cornea.

For operations, stronger solutions (up to 5%) are employed. ● Topical applications of Butyn 2% Solution are sufficient for operations in the nose and for surface anaesthesia in the throat. For genito-urinary use, Butyn gives excellent results even in cases where the mucosa is extremely painful. ● Butyn is non-narcotic and is not habit-forming. Its solutions are slightly antiseptic, stable and may be boiled. ● Butyn 2% Solution is available in 1-ounce bottles through prescription pharmacies. Butyn is also issued in 3-grain tablets and in powder form. Descriptive literature will be sent on request. The coupon is for your convenience.

THE PHYSIOLOGICAL VALUE OF THE BANANA

III. Ash or mineral matter: The amount of ash (0.8 per cent average) is high for a fruit. It is alkaline, a point to be remembered in connection with intestinal weakness.

Small quantities of iron, copper and iodine are also present.

The iron content averages 6.4 parts per million, a satisfactory amount for a fruit. The presence of a minute amount of copper assists the due assimilation of the iron into the blood.

The trace of iodine, being more readily assimilable when normally present in a food than when added in the form of a salt, has its full beneficial action upon the thyroid gland.

N.B. Therapeutically, the banana is most valuable when fully ripe. In the fully ripe banana the soluble sugars evolved are approximately 9 per cent. cane sugar and 4 to 5 per cent. each of glucose and fructose. A banana is ripe when all green has disappeared from the skin and brown spots have formed on the yellow surface.

COD LIVER OIL

*is the only Palatable Liver Oil
with vitamin content standardised
in accordance with B.P. dosage*

Cod Liver Oil well deserves its high reputation as a health-builder. For it contains nature's vital Vitamins A and D in their right proportion. It is the liver oil specifically named by the Ministry of Health and League of Nations Nutrition Committee. Its only drawback in the past has been its taste. But now we have overcome that. In "SevenSeaS" we have produced for the first time a pleasant palatable Cod Liver Oil, and it may be obtained in "High Potency" form too.

"SevenSeaS" is obtainable in three forms: (1) Standard B.P. Oil; (2) High Potency Oil—four times B.P. standard; (3) High Potency capsules containing 5 mm. dose of High Potency Oil. We would like all practitioners to prove to their own satisfaction just how revolutionary "SevenSeaS" High Potency Cod Liver Oil is. Please send to the address below for a free sample.

EFFICIENCY ESTABLISHED BY BIOLOGICAL TESTS AND CLINICAL USE

AN EXTRACT OF ADRENAL CORTEX FOR THE TREATMENT OF ADDISON'S DISEASE AND OTHER CONDITIONS

EUCORTONE is an extract of adrenal cortex, containing the hormone, cortin. It is highly successful in Addison's disease. Particularly striking is its rapid restoration of appetite, weight, strength, and feeling of well-being.

Successes have now been reported from the use of adrenal cortical extract in various other conditions, including neurasthenia, psoriasis, and hyperemesis gravidarum.

IN ACUTE TOXÆMIA OF BURNS—*Lancet*, 1936, June 20th, p. 1400.

Three cases of acute toxæmia from burns were treated with EUCORTONE and recovered. In two of the cases, death within a short time could have been predicted almost certainly. In the investigators' experience of these conditions, recovery under any methods of treatment previously used had not occurred. The investigators attributed the recovery in these cases with every confidence to EUCORTONE.

EUCORTONE is biologically standardized on adrenalectomized animals. It has now been further purified and concentrated. It is practically free from nitrogen and adrenaline, contains no irritant or toxic substance, and is sterile. One c.cm. of the extract is equivalent to 75 grams of adrenal cortex or about 110 grams of the whole gland. EUCORTONE is administered intramuscularly, intravenously (in crises), and subcutaneously (in chronic cases).

LOWER ABDOMINAL PAINS OF CERVICAL ORIGIN THEIR GENESIS AND TREATMENT*

BY

JAMES YOUNG, D.S.O., M.D., F.R.C.S., F.C.O.G.

Professor of Obstetrics and Gynaecology, University of London; Director of Department of Obstetrics and Gynaecology, British Postgraduate Medical School, Hammersmith Hospital, London; Consulting Obstetrician, Edinburgh Royal Maternity and Simpson Memorial Hospital; Consulting Gynaecologist, Royal Infirmary, Edinburgh

The Cervical Syndrome

The cervix in its short length of one inch is unique in that, while it is freely exposed below to external injury and infection, above it is in immediate relation to the abdominal cavity and its sensitive peritoneal lining. Further, it is significant that the cervix is the sole region in the body in which a relatively simple damage is prone to persist as a permanent sore. The general pathological features of this common lesion are well known and need not be discussed here.

Alike in its frequency and in the suffering with which it is associated, the cervical syndrome constitutes one of the most important entities in gynaecology. In its typical form it possesses certain characteristic features which I first described in 1930 (Young, 1930) and which may be stated shortly as follows:

Characteristic Features

1. It is predominantly a condition found in parous women, and in a large majority it can be traced historically to the last birth or abortion. In a more or less consecutive series of 349 such patients admitted to hospital under my care, 304, or 87 per cent., were parous, and the puerperal correlation was evident in nearly 90 per cent. of these.

2. The main symptom is chronic distress and pain situated in the lower abdomen and, less commonly, in the lumbosacral area of the back. Dyspareunia is almost invariably present: the condition is the most important cause of dyspareunia in parous women.

3. Leucorrhoea coinciding chronologically with the pain, or not infrequently preceding it, is a common feature.

4. There is an absence of gross pelvic pathology, and this, combined with the marked local and general symptomatology, is a common cause of confusion in diagnosis and of error in treatment. The lesion underlying the syndrome is generally caused by the trauma of labour, on which a chronic inflammation of the cervix is implanted. The existence of a similar lesion without pre-existing trauma explains the relatively rare cases found in nulliparae.

5. While chronic ill-health is a common end-result, the abdominal distress may often extend over a long period without producing any corresponding deterioration in the general state of the patient. At the same time, from an early

stage there may be profound systemic disturbance in the shape of general weakness, dyspepsia, marked nervous reactions, "rheumatism," etc., while local functional disorders may also develop early—for example, irritability of the bladder and lower bowel.

6. In a large proportion of cases treatment of a simple nature directed to the underlying lesion is strikingly successful.

The history in many instances is characteristic. Beginning with some such expression as "ever since the birth of my baby," it tells of years drawn out with an agony both of spirit and of body. As it unfolds one can recognize the young, healthy, and buoyant bride becoming gradually transformed into the ailing matron, plaintive, peevish, sleepless, and dyspeptic, who, as in Jane Austen's Mary Musgrove, has formed a theme for easy sarcasm throughout the ages. The branks and the ducking-stool were the treatment meted out to such "scolding wives" in former days. We have tempered the harshness of those more inhumane times, but it is doubtful if we have in any great measure relieved the misery of this large population in our midst. The present inquiry had its origin many years ago in the gradual recognition, among the chronic sufferers in a busy gynaecological clinic, of a large group with an essentially similar complex, for whom, in the absence of any clear underlying pathology, no adequate treatment was possible. Many, indeed, belonged to a considerable and a peculiarly distressing class in that they had suffered frequent and varied operative treatment, both minor and major, without benefit. The scarred abdomen often witnessed to multiple operations during which in succession, it might be, the appendix and the ovaries had been removed, the womb had been fixed, and, finally, in a last desperate effort, the pelvis had been swept clean. Some of us have seen many examples of such shattered lives. It is not surprising that in a large number the mental state should have given rise to anxiety for which, as revealed in the history, the psychiatric specialist had been summoned. Recently I saw one such woman who for twenty-three years had suffered from more or less constant abdominal distress and whose organs had been removed at successive operations. The diseased cervix alone had escaped! Within a few days of treatment directed to this lesion the abdominal pain had gone, and six months later her life and health had been completely revolutionized.

* Based upon the Honorary Presidential Address to the Glasgow University Medico-Chirurgical Society, October 28, 1937, and the Annual Address to the Oxford Medical Society, November 12, 1937.

FOR INVALIDS**

'PANOPEPTON' can be relied upon in cases where the nutrition of the patient is of prime importance.

'PANOPEPTON' is the most nutritious, the most agreeable and reliable, the **BEST** of all foods for the sick.

Supplied in 12-oz. bottles.

'PEPSENCIA'

'PEPSENCIA' is an ever-ready digestive fluid, containing all the soluble constituents of the gastric juice preserved in an agreeable aromatic menstruum.

It represents both the peptic and milk-curdling ferments obtained directly from the fresh peptic glands.

*Supplied in four sizes:
4-oz., 8-oz., 16-oz., and W. Qts.*

Originated and Manufactured by—
FAIRCHILD BROS. & FOSTER (Inc. N.Y.), NEW YORK, and 65, Hellera Road, London, E.C.1

Agents—
BURROUGHS WELLCOME & CO., LONDON, SYDNEY, and CAPE TOWN.

restriction to one iliac fossa exhibit a preponderance on the left side in the proportion of about four to one.

Mesial Visceral Pain

Although this does not ordinarily constitute the main pain symptom, I will discuss it first because it would seem in its genesis to possess the features which are generally ascribed to a visceral pain. It is expressed in two clinical forms: (a) As a *spontaneous* discomfort or actual pain vaguely located to the retropubic area and lower mesial abdomen (Fig. 1). It is rarely present alone,

FIG. 1.—Mesial visceral pain. Typically this is low in situation and it is poorly localized. It is present as (a) spontaneous and (b) excitation pain.

and it is not associated with hyperalgesia, muscular rigidity, and local tenderness on pressure. Its main and almost invariable clinical manifestation is (b) as a pain felt immediately when the finger placed in the vagina exerts pressure against the cervix. Under these conditions the sensation may be acute, and in severe cases may cause the patient to cry out because of its intensity. Typically the patient has difficulty in locating it; she may state that it is felt deeply in the pelvis or she may place her hand somewhat vaguely over the pubes and lower abdomen. In the indefiniteness of its mesial localization it at once suggests the true visceral pain of other diseased states. To the pain excited by pressure on the cervix in this manner I have applied the term *visceral excitation pain*.

To appreciate the significance of this excitation pain we have to remember that in health the cervix may be moved in any direction through a considerable range without pain being elicited. The fact that in a typical case pain can be induced by even the slightest pressure endows it therefore with a considerable clinical significance. In passing it may be remarked that fixation of the cervix by contracture in traumatic or inflammatory tissue is a common finding in cases exhibiting this sign. Displacement of the organ is also not infrequent, either laterally or posteriorly, although, as I have elsewhere shown, this displacement may in some cases be due to muscle spasm, which disappears under anaesthesia and after treatment. Further, although a lesion of the kind which we have previously described constitutes the essential causal factor, in many instances, and so long as the inflammatory condition is limited to the lower vaginal cone of the cervix, both the spontaneous and the excitation pains may be absent. Moreover, it is notorious that even when the external and visible signs of infection have resolved after treatment the pains may persist, either

because of a remaining more deep-seated inflammatory change or because of the sensitiveness of the residual scars. The complex sometimes follows trauma that results in scarring without the supervision of any external evidence of infection. It is clinically important to observe that in cases exhibiting excitation pain *dyspareunia* is both a characteristic and a distressing symptom. The condition indeed is the most common cause of dyspareunia in the parous woman.

A further point of considerable importance to note is that the cervix itself in these cases often acquires a true inherent sensitiveness. In the healthy woman the cervix, like other hollow abdominal viscera, can be subjected to ordinary trauma without the creation of pain. It can, for example, be seized between the blades of a vulsellum forceps without suffering being caused. In the condition under discussion this insensitiveness is often abolished. The cervical lips are no longer immune to even such mild trauma, and in exceptional cases, indeed, I have found that the gentle pressure of a probe against the cervical surface may elicit a severe pain reaction. These pains all possess the vagueness of localization, characterizing the ordinary excitation pain.

Iliac Fossa*Referred Pain

This, the dominating symptom in a typical case, may be present in both sides of the lower abdomen. Characteristically, however, it is restricted to one side, more commonly the left. The pain distributed in this way exhibits itself: (a) as spontaneous pain, (b) as local tenderness, and (c) as well-localized excitation pain. The *spontaneous pain* may consist of an aching, ever present during the waking hours, or, more commonly, of a pain which comes and goes, being prone to aggravation before

FIG. 2.—Referred pain. Typically this is situated in one or both sides of the lower abdomen. Where unilateral it is more often on the left side. It is present as (a) spontaneous pain, (b) cutaneous hyperalgesia and deep tenderness, and (c) excitation pain. Deviation of the cervix to side of pain is common.

menstruation and during exertion. It may be widely spread over the lower lateral quadrant or it may be more localized. It is associated with *local tenderness*, often over a smaller area, which is usually easy to delimit. In many instances it is restricted to a segment about two inches square lying below and external to the umbilicus. There is generally an associated hyperalgesia of the skin, but muscular rigidity is typically absent. A further observation almost invariably made is that where this referred

The Pain Element

In this place we are specially concerned with the pain element in the cervical syndrome; later pages will be devoted to a study of its genesis and treatment. The relatively scant attention which in the past has been given to the diseased cervix as a source of chronic abdomino-pelvic pain is due to three considerations: (1) the common clinical observation that cervical trauma and infection may be painless; (2) the well-known fact that, like other hollow viscera, the healthy cervix is insensitive to stimuli which provoke pain on surface tissues; (3) the frequent persistence of pain in women whose uterus has been completely removed for severe cervical infection. At first sight this triple argument would seem to have much force behind it. At the same time, as we shall attempt to show further on, each item is relevant only in so far as it fails to take into account all the available data. Thus in regard to (1) and (2) it is easy to demonstrate that in certain conditions the diseased cervix, so far from being insensitive, may acquire a most acute sensitiveness to stimuli which ordinarily are completely painless. In respect of (3) the conditions after removal of the cervix often resemble those found in a painful scar left after an operation in a sensitive area.

Visceral Pains

Before we pass on to consider the nature and the genesis of the pain phenomena of our syndrome a brief reference must be made to the present position of our knowledge on the causation of visceral pain in general. It is a common observation in abdominal symptomatology that the hollow intraperitoneal viscera, which are mesially situated in regard to their embryonic development, may in disease be concerned in the production of two completely different types of pain: (a) true visceral pain, and (b) referred or reflex pain. The viscera themselves are insensitive to the stimuli that ordinarily provoke pain on the body surfaces—for example, cutting, burning, etc.—but it is now generally agreed that pain is appreciated by a viscus when it is exposed to those intrinsic influences which are prone to disturb its function. Such visceral sensations have certain characteristic and well-defined features. In the first place, they are typically, if not always, *mesial in situation*—the epigastrium in the case of the stomach, above and around the umbilicus in the case of the small bowel and appendix, and below the umbilicus in the case of the large bowel; in the second place, such true visceral pains are usually only *imperfectly localized* by the patient; and, thirdly, they are *unassociated with hyperalgesia of the corresponding area and muscular rigidity of the corresponding part of the abdominal wall*. A common example of such mesial visceral pain in a lateral organ is the initial umbilical pain occurring in obstructive appendicitis. Referred or reflex pain is felt on the body surface at a site which in general is determined by the location of the organ, though it may be projected on to a distant area of the abdominal wall or other somatic surface. Such referred pains are typically *associated with hyperalgesia and muscular rigidity*, and they are therefore *well localized*.

It is now generally agreed that while true visceral pain is felt directly in the organ through the medium of the splanchnic nerves, its site is determined by the spinal segment corresponding to the primitive development of the organ. Referred or reflex pain, on the other hand, has been the topic of much controversy. Until recently the explanation generally accepted was that of Mackenzie (1920), who postulated that the stimuli originated in the

diseased viscus and were referred via the sympathetic nerves to the cord, where they created an "irritable focus." In this view a simple surface stimulus which is innocuous under healthy conditions is, by its passage through this irritable focus in the corresponding spinal segment, now appreciated as pain by the higher centres. This was Mackenzie's viscerosensory reflex, the muscular rigidity in the same surface area arising from a visceromotor reflex based on a similar segmental arc. The work of Morley (1931) and others has cast serious doubt on the validity of these conceptions, and there is now evidence that referred pain, with its associated hyperalgesia, muscular rigidity, and tenderness, is dependent not upon visceral impulses but upon impulses derived from a secondary irritation of the adjacent peritoneum—the so-called peritoneo-cutaneous and the peritoneo-muscular reflexes of Morley. Thus the site of the referred pain depends upon the site of the peritoneal irritation. The pain in the iliac fossa in a typical case of appendicitis, for example, is referred segmentally to the abdominal wall not from the appendix itself but from the inflamed parietal peritoneum. In support of this view Morley quotes the observation that the site of surface tenderness in gastric ulcer varies with the position of the stomach within the abdomen. A further common example pointing a similar lesson is found in ectopic pregnancy. The referred pain in this condition is localized to the iliac fossa when the extravasated blood is located in the pelvis and lower abdomen, but when, as often happens, the fluid blood flows upwards to the under surface of the diaphragm provokes the shoulder pain of phrenic stimulation.

The intrinsic mechanism underlying the actual sensation at the referred site has given rise to much speculation. That the skin and other structures of the abdominal wall are directly concerned is proved by the observations of Lemaire (1926) and Morley (1931), who abolished the spontaneous pain by means of a local anaesthetic applied to the corresponding skin area. Morley (1931) found that this procedure did not necessarily abolish deep tenderness. That the referred sensation is dependent not on an alteration in the "sensitiveness" of the higher nerve levels, such as Mackenzie and others have postulated, but on some local change induced at the nerve terminals in the skin, has been put forward by some writers. Verge (1927), for example, has suggested that the original stimulus in the abdomen induces reflex vasomotor changes in the corresponding segmental skin, while Spamer and Lunedei (1927) suggest that centrifugal impulses passing to the skin result in local biochemical changes. Recently Lewis (1937) has adduced striking evidence for the view that the spreading hyperalgesia round a focus of damaged skin is dependent upon stimuli which radiate along a specialized type of nerve—named by him the "nociceptive nerves"—to the distant areas and there induce biochemical changes. In this way the threshold for pain of the ordinary sensory nerves in the corresponding area is lowered. Lewis's work so far has concerned itself with the demonstration of the peripheral manifestations of this phenomenon.

The Lesion and its Pains

I have already indicated that the dominating symptom in the complex which is the subject of this discussion is abdominal pain. In some cases the area of pain and tenderness may be widespread over the abdomen, but in the large majority it is restricted to the lower abdomen. In a typical case the chief emphasis is found in the iliac fossae, and especially the left iliac fossa. Cases have

That the visceral and referred pains have such a separate and distinct anatomical basis is supported by two further observations: (i) one pain may exist without the other, and (ii) the procedures directed to nerve blockage may on occasion exert a differential selection in

FIG. 3.—Speculative origin of (A) visceral and (B) referred pains.

respect of the two pain phenomena. Thus it sometimes happens that complete relief in one set of pain phenomena is obtained without the other being affected: infiltration of one side with procaine may abolish the referred pain in the corresponding iliac fossa and leave the visceral pain unaffected till similar blockage of the opposite side is carried out.

Low Back Pain

Pain in the lumbo-sacral area is commonly present in women who exhibit the abdominal pain syndrome. Where the symptoms show the puerperal correlation the backache may either date from the latter months of pregnancy or, more commonly, it may only appear after—sometimes some weeks or months after—childbirth. The factors responsible for the common backache of parous women are still obscure, and the wider issues of the subject are not germane to the present discussion. Suffice it to say that from a somewhat confusing symptomatology we can assemble with a degree of precision three more or less definite and distinct clinical conditions: (a) backache directly due to genital prolapse and major pelvic disease, which in each case responds to the appropriate treatment; (b) backache which is orthopaedic in origin and due to involvement of the sacro-iliac or lumbo-sacral joints (cases with a puerperal correlation are often immediately relieved by manipulation—forcible flexion and extension of the spine and rotation at the sacro-iliac joints); and (c) cases that are associated on the one hand with no evidence of joint pathology, and on the other with no pelvic disease except the lesion which has been discussed on the preceding pages. Here excitation pain, poorly localized and referred to the corresponding area in the back, is typically found, and dyspareunia is usually a prominent clinical feature. In such cases blockage of the pelvic nerves is generally successful.

Cases Illustrating the Effects of Nerve Blockage

In the following short clinical records the method which we have latterly introduced for the routine treat-

ment of our cases is made clearer than is possible in the text. The employment of procaine as a routine procedure enables one to determine the extent to which relief may be expected in any individual case by the placing of the procaine. It provides at the same time a valuable method of studying the nature and response of the various elements in the pain complex.

CASE I

A 3-para, aged 29, whose last pregnancy ended in miscarriage five years ago.

Complaint.—Leucorrhoea, five years; pain in the left iliac fossa, aggravated pre-menstrually, five years; dyspareunia, five years; frequency of micturition, diurnal and nocturnal.

Examination and Treatment.—October 26, 1937, 10 a.m.: There was no tenderness in the abdomen. The cervix was infected and was mobile; excitation pain was present in the low mesial abdomen, poorly localized. 10.17 a.m.: 10 c.cm. 1 per cent. procaine, left side. 10.20 a.m.: 10 c.cm. 1 per cent. procaine, right side. 10.27 a.m.: Excitation pain gone. 10.40 a.m.: 10 c.cm. proctocaine, both sides. 10.43 a.m.: cauterization of cervix and puncture of Nabothian follicles. November 1, 10.30 a.m.: Excitation pain gone; discharged from hospital. December 23: No spontaneous or excitation pain; dyspareunia, frequency, and leucorrhoea completely relieved.

CASE II

A 2-para, aged 55; last pregnancy eighteen years ago; menopause four years ago.

Complaint.—Leucorrhoea, thick and yellow, one year; pain in left iliac fossa, constant and marked, one year; pain in low back, three months; dysuria and urgency; severe constipation with marked dyspeptic symptoms, pain on movement of bowels; health depreciating, loss of weight, fainting attacks.

December 17, 1936: X-ray investigation to exclude bowel neoplasm—negative; no x-ray evidence of abnormality in spine or pelvic joints. December 24: Physician diagnosed "spastic constipation." January 2, 1937: Surgeon found no trouble in sacro-iliac or lumbo-sacral joints: "Redundancy in rectal mucosa three inches from anus. Area acutely tender. In view of the negative x-ray and laboratory findings I think this is part of an abdominal hypersensitiveness associated with her enteroptotic condition. Her caecum and ascending colon to-day are hyperresonant and the liver dullness is reduced."

Examination and Treatment.—January 10, 1937, 10 a.m.: Spontaneous pain, diffuse over lower abdomen, marked in left iliac fossa; tenderness and superficial hyperalgesia in iliac fossae—marked in left; excitation pain very marked in left iliac fossa. 10.15 a.m.: Endocervical polypus removed; 10 c.cm. 85 per cent. alcohol on each side. January 11: No spontaneous pain, no local tenderness, no excitation pain, no pain on movement of bowels; discharged from hospital.

January 20: As above; general condition very much improved. February 2 to 9: Readmitted because of swelling of left ankle: abdominal condition satisfactory. March 24: Pain in right and left iliac fossae; tenderness and excitation pain have recurred. June 2: Diffuse lower abdominal spontaneous pain, especially in left iliac fossa and extending downwards on inner aspect of left thigh; marked cutaneous hyperalgesia and tenderness in both iliac fossae, especially left; excitation pain in left iliac fossa. June 4: Cervix healthy; proctocaine, 10 c.cm. left side, 5 c.cm. right side. June 6: Spontaneous pain, tenderness, and excitation pain gone. September 15: Feels well; putting on weight; constipation still severe; slight pain in lower abdomen. October 6: Pains and aches, have recurred as bad as ever. October 16, 9 a.m.: Spontaneous pain diffuse lower abdomen; cutaneous hyperalgesia and tenderness in both iliac fossae, especially left; excitation pain in left iliac fossa. 9.15 a.m.: 10 c.cm. 1 per cent. procaine, left side. 9.25 a.m.: Tenderness and excitation pain unrelieved; 10 c.cm. 1 per cent. procaine, right side. 9.28 a.m.: Tenderness right side gone, tenderness left side unrelieved; excitation pain unrelieved. 9.35 a.m.: 6 c.cm.

segment of spontaneous pain and local tenderness exists pressure on the cervix at once excites pain in an acute and well-localized form in the same area. To this phenomenon I have applied the term *referred excitation pain* (Fig. 2). Excitation pain of this kind is more frequently encountered than the visceral type already described, and it constitutes the main manifestation of the dyspareunia complained of by the majority of such women.

Data Obtained from the Effects of Treatment

Local Treatment.—Before proceeding to a further discussion of this problem it is necessary to interpolate some data derived from the results of treatment directed to the cervical lesion. In a previous communication (Young, 1930) I reported a follow-up of sixty-seven cases over a period varying from two to twelve months subsequent to the routine treatment which we adopt in such cases—namely, dilatation of the cervix, radial incision of the infected area with the electric cautery, and deep puncture of the tissues, including evacuation of the gland cysts which are found in a large proportion of the cases. In thirty-three, or 49 per cent., there was complete relief of pain, whilst in twenty-one, or 31 per cent., there was partial relief. Including a further series of 116 cases we now have records of 183 cases unassociated with any other recognizable lesion, showing after this simple procedure a cure of pain in eighty-five, or 46.4 per cent., and cure or partial relief of varying degree in a total of about 80 per cent. In a number of the partial or complete failures a repeat operation effects entire clinical recovery.

Blockage of Pelvic Nerves.—Despite the good results of these measures, a considerable proportion obtain little or no relief, and in 1932 (Young, 1933) I introduced for this class of case a method aiming at blockage of Frankenhäuser's plexus by an injection into the base of the broad ligament along the side of the cervix of 5 to 10 c.cm. of 85 per cent. alcohol, after the procedure adopted successfully for the treatment of trigeminal neuralgia. In the preliminary communication published in 1933 I recorded eight cases so treated, with relief in seven. Since then I have employed this method in forty-eight cases, with complete immediate relief in forty-one—that is, with a percentage success over both series of 85.7. In my preliminary paper I noted—and this has been borne out in the larger series—that the relief so obtained often only lasts for two or three months, and that for these cases repetition of the procedure is necessary. Recently, however, Sutherland (1937) has employed procaine (benzyl alcohol 5 per cent., butyl-p-aminobenzoate 6 per cent., olive oil to 100 per cent.) as a substitute for alcohol, and claims complete relief maintained over the period studied (three to twenty months) in twenty-six out of fifty cases, or 52 per cent., and partial benefit and cure in 42, or 84 per cent. For the last six months this procedure has been adopted in my clinic, and although the period is too short to allow of a conclusive statement I have gathered the impression that the method is an improvement on that in which alcohol is used. In parenthesis I would here state that in order to give the patient reporting for the first time the maximum chance of relief it is now my custom to employ a regime in which the treatment directed to cervical drainage is combined with nerve blockage.

The relief conferred by the procedures just mentioned is not restricted to the alleviation of the pains which we have described as characterizing the majority of the cases.

Apart from the improvement in the general health and well-being of the patients, which is often rapid and striking, there is in an otherwise successful case usually an immediate relief in the *bladder irritability*, often a distressing element in the syndrome. In the majority of instances this is unassociated with any abnormal constituents in the urine or any evidence of organic lesion in the urinary tract. Within a relatively few hours after the cervical drainage and the nerve blockage the urinary symptoms (diurnal and nocturnal frequency and occasionally dysuria) clear up. It would seem legitimate to assume that these functional disturbances are dependent upon nerve irritation. In some instances there is, in addition, pain related to the bowel and associated with defaecation; in such cases excitation pain may be referred to the back passage. Relief in these respects is also usual.

From what has been said it will have become apparent that there is a small group comprising those who fail to respond to any of the therapeutic measures which we have so far been able to devise, and there is a considerable group of patients in whom the response is only temporary. These groups at the moment are the subject of special study. In some instances relief may be obtained by hysterectomy, although this is by no means certain: out of five such cases the pain persisted in two. Presacral neurectomy, as practised by Cotte (1928) for intractable pelvic pain, fails to give relief in this condition (Young, 1933). Of course in the recalcitrant case a possible error in diagnosis must not be overlooked; this aspect of the subject I shall consider on a subsequent page.

Anatomical Basis of the Visceral and Referred Pains

Visceral Pain.—The mesial and low situation of this pain (corresponding to the twelfth dorsal and first lumbar nerves), its poor localization, and its freedom from any accompanying local tenderness, taken in conjunction with the method in which it is evoked by excitation, all strongly suggest that it arises in the cervix or immediately adjacent tissues. While its actual genesis cannot be established with certainty, the readiness with which it responds to procedures directed to blockage of the nerves at the side of the cervix is in keeping with the view that the nerve stimuli pass upwards along Frankenhäuser's plexus (the inferior hypogastric plexus), the rich bundle of sympathetic fibres which on each side form the downward extension of the superior hypogastric plexus of so-called presacral nerve. These plexuses reach the cervix on each side after encircling the ampulla of the rectum.

Referred Pain.—The relatively high situation of this pain (corresponding in a typical case to the tenth, eleventh and twelfth dorsal segments), its more or less precise localization in the side of the abdomen, and its associated hyperalgesia and local tenderness, all by analogy strongly suggest that it is not directly visceral in origin and that it should be classed among the referred pains, while at other sites are peritoneal in their genesis. In the absence of reliable data it is impossible to ascribe to this an accurate pelvic source, but the circumstances, including their easy excitation by cervical pressure are in keeping with the view that they arise from irritation extending beyond the confines of the cervix to the adjacent peritoneum of the pouch of Douglas or broad ligament. In Fig. 3 I have, in diagram, represented the supposed source of the (A) visceral and (B) referred pains. According to such a conception we must assume that the nerve blockage succeeds because it includes the fibres of both irritable foci—cervical and peritoneal.

remove a large—I believe the largest—group, which is easily recognized by its well-defined clinical features. It may be claimed with justice to have effected a veritable clearance in a lumber-room of diagnostic confusion. Most of us can recall the days when the chronic abdominal pains which are the subject of this study were ascribed to conditions as unsatisfying to the conscientious clinician as they were ill founded in pathology—for example, varicocele of the pampiniform plexus, sclerotic ovaries, ovaritis, prolapse of the ovary, constipation, adhesions, neurasthenia, etc.

The absence of gross pelvic and abdominal pathology and the puerperal correlation usually suffice at once to distinguish the syndrome from the major causes of lower abdominal pain—neoplasm, endometrioma, diverticulosis, appendicitis, etc. In subacute and chronic salpingitis there may be confusion, especially where the history dates from childbirth or abortion, but the presence of a tender, fixed, often bilateral mass in the posterior pelvis generally establishes the diagnosis. In some few cases the syndrome may be simulated by endometrioma; but here the puerperal correlation is usually absent, and whereas the former is very common in young women endometrioma is more frequent in later years. In endometrioma, moreover, the characteristic tender and fixed mass in the pouch of Douglas is often found. At the same time in women over 30 with a menstrual exacerbation of the pain endometrioma should always be considered. A chronic pelvic appendicitis may sometimes closely simulate the condition, though here again the characteristic puerperal dating is generally absent. It should be remembered that in such conditions as salpingitis, endometrioma, and pelvic appendicitis, where a tender swelling is present low in the pelvis, vaginal excitation pains are usually easily elicited, and therefore they cannot of themselves be regarded as of great value in the relatively rare cases which are in doubt. A common source of clinical confusion is in regard to recurrent appendicitis, and it is notorious that a large number of women with right iliac fossa pain have had their appendix removed before coming to our clinic. It is of the utmost importance that the surgeon should be more familiar with this common source of iliac fossa pain and its diagnosis. The easy establishment of referred excitation pain in the right side and its immediate removal by nerve blockade are the main diagnostic aids.

Finally, it is important to remember that in a large number of gynaecological conditions a serious error in diagnosis may arise from a failure to recognize that iliac fossa pain may spring not from the more apparent pathology, such as retroflexion, genital prolapse, etc., but from the frequently coincident cervical lesion. The institution of treatment appropriate to this lesion may eliminate the indication for more major treatment; where major measures are required the associated syndrome should be dealt with at the same time.

CULTURAL METHODS IN BACTERIOLOGICAL DIAGNOSIS OF TUBERCULOSIS

BY

C. A. GREEN, M.B., D.P.H.

(From the Bacteriology Department, Edinburgh University)

Using the Jensen (1932) modification of the medium introduced by Löwenstein (1930), Holmes (1934) drew attention to the value of cultivation in the diagnosis of tuberculosis. Of the many observations of similar nature may be mentioned those of Hohn (1926), Sweany and Evanoff (1928), Bezaçon and Buc (1931), Herrold (1931), Corper (1932), Danbolt (1935), Cummins and Duggan (1934), and Mishulow and others (1934). Shrewsbury and Barson (1937) noted successful results following the introduction of cultivation as part of the routine investigation of selected specimens of sputa. In order to determine the practical value of the method the same procedure has been adopted in this laboratory with all specimens in which an examination for *B. tuberculosis* was requested, and the results obtained over a period of two years are here recorded. Sputa from recognized or clinically suspicious cases of human tuberculosis comprised the bulk of the material examined, which also included specimens of urine, pleural fluid, milk, and cerebrospinal fluid. The previous routine examination was adhered to and the results compared with those secured by the additional aid of cultivation.

Methods

Routine Examination.—The examination of sputa consisted in the usual microscopical examination of films stained by the Ziehl-Neelsen method. The finding of acid-fast and alcohol-fast bacilli morphologically identical with *B. tuberculosis* was reported as a "positive" result, the absence of such forms being reported as "tubercle bacilli not found." The same procedure, preceded if necessary by centrifugation, was adopted with all other specimens save in the case of milk. Guinea-pig inoculation was carried out in specimens other than milk only if special request was made, but in examining milks the animal test was invariably utilized.

Cultural Methods.—If the specimen received was likely to be free of organisms other than tubercle bacilli—for example, cerebrospinal fluid withdrawn at lumbar puncture—the centrifuged deposit of such specimens was directly inoculated on culture media without further treatment. In the presence of contaminating organisms the material was first centrifuged if necessary. The deposit was then suspended in 2 c.cm. of the supernatant fluid, acidified for thirty minutes by the addition of an equal volume of 6 per cent. hydrochloric acid, and neutralized by the addition of 4 per cent. sodium hydroxide. The centrifuged deposit was then inoculated by means of a sterile Pasteur pipette on culture media. In a previous examination of a large number of cerebrospinal fluids and specimens of pus for tubercle bacilli the preliminary acid treatment had been successfully used, and the same procedure was therefore adapted to the examination of sputum instead of the usual alkali method.

The culture media most frequently used were the Löwenstein-Jensen medium and a modification of the same in which the glycerin content was omitted. All specimens were cultured on both media in screw-cap bottles. Considerable economy in incubator space and the easy handling of large numbers of bottle cultures were secured by the use of a rack consisting of a wooden

more of procaine, left side. 9.40 a.m.: All pain and tenderness gone; 8 c.cm. procaine each side. October 17, 10 a.m.: No pain, slight tenderness left iliac fossa. December 2: No spontaneous pain, tenderness, or excitation pain; dysuria and frequency completely relieved; general condition much improved.

CASE III

This patient, aged 22, had her first child one year ago; spontaneous birth.

Complaint.—Leucorrhoea, copious and offensive, one year; pain over sacral area of back, nine months; dyspareunia, nine months; tired, loss of energy—formerly well and vigorous.

Examination.—Nothing abnormal was seen in the abdomen, and there was no local tenderness in the back. The cervix was infected, fixed, and markedly retroposed; severe pain was felt "deep down towards the back" on moving the cervix; poor localization.

Treatment.—October 29, 1937, 11.15 a.m.: Severe excitation pain deep in pelvis—badly localized; caused patient to cry out. 11.18 a.m.: Pain on grasping cervix with vulsellum. 11.24 a.m.: 8 c.cm. 1 per cent. procaine, left side. 11.25 a.m.: 8 c.cm. 1 per cent. procaine, right side. 11.32 a.m.: Excitation pain gone. 11.35 a.m.: 10 c.cm. procaine, right side. 11.37 a.m.: 10 c.cm. procaine, left side. 11.40 a.m.: Cauterization of the infected cervix. November 1: No spontaneous pain in back since operation; no excitation pain. December 23: No spontaneous pain, tenderness, or excitation pain; dyspareunia and leucorrhoea completely relieved.

REMARKS ON CASES I, II, AND III

Cases I and III are common examples in young women of the comparatively early and generally easily curable stage, in which drainage of the cervix is often alone sufficient to effect relief. The recognition of the condition at this early stage is important if the patient is to be protected against a long period of suffering, with the production of a far-reaching systemic upset. Case II is an example in an older woman of the more intractable condition in which treatment effects only a temporary relief. Here the problem is more difficult, for while treatment succeeds in curing the active cervical disease, it does not clear up the pain arising in the residual "scars" for more than three months. Major surgical procedures give no assurance of relief, and such cases in the past have tended to bring surgery into disrepute.

General Discussion

The above observations would seem to make it clear that within the ambit of the one syndrome there are two essentially different pain mechanisms. They differ, first, in regard to the site at which the pain is felt in relation to the body surface and, secondly, in regard to the inherent nature of the sensations experienced. The separateness of the two phenomena lends support to the argument of Morley that the visceral and referred pain mechanisms employ different kinds of nerve tracts. Morley has suggested that, while the splanchnic nerves subserve the visceral mechanism, the cerebrospinal nerves are concerned with that of referred pain and tenderness.

To the student of pain genesis these phenomena, as seen in their somewhat crude form by the clinician, open up intriguing lines of investigation. There are surely few fields in medical research in which the anatomist and physiologist can with more signal advantage be ranged alongside the clinician in pursuit of a common end. Among the many problems that await solution there are two which stand out because of their clinical bearing. The first concerns the study of the nervous arc by which the impulses originating directly or indirectly from visceral

disease are eventually registered on a somatic surface as pain. In this connexion the experimental work of Pollak and Davis (1935) has already suggested that the arc involved in the referred pain produced by irritation of the diaphragmatic terminals of the phrenic nerve is more complex than is generally believed. According to these observers the posterior roots, four segments of the cord, the efferent sympathetic fibres, the cervical sympathetic ganglia, and the sensory nerve endings and sensory nerves of the cerebrospinal system are all implicated.

The second problem relates to the intimate meaning of the various subjective reactions. Take for example the two clinical manifestations of the visceral pain—that which is spontaneous and that which is elicited by excitation. In so far as these are both conceived as arising in and being felt in the viscus, although registered at a site depending upon the spinal segment affected, they may be regarded simply as originating from one and the same local factor, which in the case of excitation is merely increased in intensity. In respect of the referred pain complex, on the other hand, the facts do not lend themselves to such an easy theoretical interpretation. Here the pain would seem to be more definitely felt at the site of registration, whether spontaneous or excited or in the form of tenderness. The interpretation of this, the feature which specially distinguishes the referred phenomena, is not affected by the choice we make between the two competing views of the essential mechanism involved—that whether we regard the reference to the distant somatic site as merely due to the creation of an irritable focus in the corresponding segment of the cord or whether we postulate a stimulus sent along the segmental arc to the somatic tissues with the production of biochemical changes at the sensory terminals. The existence of superficial hyperalgesia and local tenderness as an ingredient in the referred complex necessarily implies that the tissues at the site of registration enter into the scheme, though it is true that it cannot be argued from this that the spontaneous and excitation pains of necessity also depend upon the same superficial nerves for their appreciation. I have attempted to test this question by observing the effects of local anaesthesia applied to the abdominal wall. In general it is found that while local anaesthesia of the skin abolishes superficial hyperalgesia it does not affect the local tenderness or the excitation pain. Anaesthetization of the entire thickness of the abdominal wall from skin to peritoneum, which is necessary for a complete test, has not so far been employed. In any case there would seem to be a distinct difference between the mechanisms of tenderness and excitation, in that while the former implies a lowering of the threshold for pain in response to the pulses previously discharged from the primary lesion, it is difficult to explain excitation pain at the same distant site except on the basis of a new reflex stimulus which its appreciation is independent of the threshold mechanism as this is ordinarily understood. In other words, when stimulation of the sensory terminals at the surface is necessary for the eliciting of the tenderness, there is no evidence that such is necessary for the eliciting of excitation or, for that matter, of the spontaneous pain. That tenderness and spontaneous pain are dependent upon a continuous flow of stimuli from the primary source is proved by their immediate disappearance after block of this source with procaine.

Some Points in Differential Diagnosis

The establishment on a sound basis of the complex syndrome enables us, from the varied conditions responsible for chronic abdominal pain in women, at least

Accordingly a questionnaire was prepared and sent to clinicians in charge of those cases in which a negative direct film examination was followed by a positive cultural report. Of the fifty-five replies received the bacteriological findings were confirmed in fifty instances by clinical examination, x rays, or other means. In twenty-nine cases the clinician was reasonably certain of his diagnosis, but the cultural report served to place the matter beyond all doubt. Illustrative of this type of case are the following.

Case 1.—This man, aged 55, was suspected clinically of having pulmonary tuberculosis of the fibroid type, but repeated tests by direct film examination were invariably negative. The clinician observed that "the positive result in culture revealed an active condition which previously had only been suspected."

Case 2.—A woman aged 22, in whom the clinical diagnosis, supported by x-ray examination, indicated pulmonary tuberculosis involving principally the left upper lobe. Direct film examination was negative, but positive culture confirmed the diagnosis.

Case 3.—This patient, a woman aged 56, was diagnosed clinically as having chronic bronchitis. The clinician reported that "the physical signs were always those of chronic bronchitis and obscured any underlying tuberculous findings . . . the positive cultural result was followed by further investigations in hospital," and these confirmed the diagnosis.

Case 4.—In this patient, a man aged 22, an extensive pleural effusion developed on the left side eight months prior to examination of sputum. Repeated examinations of the fluid were negative, but coughing persisted. Direct film examinations of the sputum were negative, but on culture a few colonies of *B. tuberculosis* appeared.

In the next series of twenty cases the bacteriological findings were relatively of much greater importance in that the clinical suspicion of tuberculous infection was slight and the specimen was submitted more for the purpose of exclusion than in the hope of obtaining a positive result. The following are cited as examples of this type.

Case 5.—This patient, a man aged 60, had had a slight cough for years which ceased when cigarette-smoking was curtailed, and was thought to arise from that source. He had a bad family history of tuberculosis, but has always enjoyed fairly good general health. The positive cultural report led to x-ray examination, which revealed uniform marked opacity above the right apex with deposits in the left infraclavicular region from the first to the third rib. The only abnormality detected clinically in the chest was a diminution in breath sounds over the upper part of the left lung.

Case 6.—A man aged 39; he was considered to have entirely recovered from pulmonary tuberculosis, and had returned to work as a shop assistant. His doctor advised him to report periodically for examination, and a specimen of sputum taken at one of these visits was negative by direct examination but positive on culture. Physical examination revealed no signs of active infection.

Case 7.—A married woman aged 41. She complained of a feeling of weakness and loss of energy; physical examination was entirely negative. X-ray examination, following the receipt of a positive cultural report, revealed a right basal pleurisy and light fibrotic disease of right apex. Sanatorium treatment for six months, concluded with a further x-ray examination, which showed that the pleurisy had cleared up and the right apical lesion had apparently healed.

Among this latter group of cases were several in which the infection was almost certainly of very recent standing.

Case 8.—A typist, aged 30. This patient had had a slight haemoptysis, but otherwise she felt well. Clinically there was nothing further suggestive of active infection, but x-ray examination on the receipt of a positive cultural report indicated a lesion in the left apex. After sanatorium treatment the patient recovered satisfactorily and returned to work.

Case 9.—A male, aged 32, employed as an able seaman, complained of haemoptysis. Clinically he appeared fit and was able to carry out his duties without difficulty. X-ray examination following a cultural report indicated a lesion in the left apex. In this instance the diagnosis was of importance as regards pension adjustments, etc., but an observation period in a sanatorium fully confirmed the diagnosis.

Case 10.—A baby boy, aged 11 months, had attacks of mild pyrexia at intervals over three weeks, which were followed by signs of consolidation at the left apex. The mother was known to be tuberculous, the family history being altogether bad. The patient was found to react positively to the Mantoux test, the concentration of tuberculin used being 1 in 100,000. In this instance the culture was of the human type.

In all the above cases the cultures were derived from sputa, but the organism has also been unexpectedly demonstrated in other situations by this method.

Case 11.—A boy aged 13 complained of prepatellar bursitis of left knee. This condition had persisted for months, to a great extent varying with his general health. On account of a bad family history, a specimen of pus aspirated from the lesion was submitted for examination. No growth appeared on blood agar and no organisms were found on direct films, but tubercle bacilli were isolated on culture.

CASES WITH LESIONS OTHER THAN TUBERCULOUS

In the remaining six cases there were lesions other than those of tuberculous infection to which the patients' symptoms were attributed by the clinician in charge. The possibility that tuberculous infection was also present, however, could not be entirely discounted in any of these cases, the details being as follows.

Case 12.—A married woman aged 39 complained of frequent head colds, with subsequent irritable cough, for four years, dating from childbirth. She was ambulant, but always appeared unwell. Clinically and radiologically there was no evidence of tuberculous infection, but tubercle bacilli were isolated on culture from sputum.

Case 13.—A woman aged 40 was admitted to hospital with "meningitis of doubtful origin," later considered to be cerebrospinal meningitis on clinical grounds and on the isolation of meningococci from cerebrospinal fluid in the hospital laboratory. A specimen of fluid submitted to this laboratory for verification was found to show no organisms in direct films and no growth on blood agar, but tubercle bacilli were isolated on culture. The patient recovered without further developments and was discharged apparently well.

Case 14.—A man aged 63 was admitted to hospital as a case of congestive heart failure. Clinically there was no evidence of tuberculosis, although x-ray examination revealed a gross right basal lesion, probably encysted fluid. On culture tubercle bacilli were isolated from sputum.

Case 15.—A married woman was diagnosed clinically as suffering from severe bronchitis complicated by pyelitis. Ordinary physical examination revealed no sign of tuberculous disease of the lungs, and the bronchitis cleared completely following recovery from pyelitis. No x-ray examination was made. Culture of the sputum for tubercle bacilli was successful.

Case 16.—A married woman aged 32 was under observation for pulmonary tuberculosis, but no evidence was obtained other than the isolation of tubercle bacilli from a specimen of sputum. There appeared to be considerable doubt as to the diagnosis in this case, as x-ray examination carried out four years previously was negative but had not been repeated. The possibility of a right apical lesion was not entirely ruled out.

Case 17.—This male patient complained of symptoms indicative of an intrathoracic lesion on the left side. The sputum was blood-stained, but showed no tubercle bacilli in direct films, although a growth of this organism was present on

board, one inch in thickness, drilled with holes just large enough to hold the base of a bottle and fitted with a plywood base. In a rack eight inches by twelve inches were carried forty-eight cultures, the flat surface presented by the tops of the bottles enabling racks to be piled one above the other, while still permitting free passage of air and uniform heating of the cultures. Incubation was continued at 37° C. for four weeks, and all cultures were then examined. Films of suspect cultures were stained by the Ziehl-Neelsen method, and on finding the morphologically typical acid-fast bacilli the pathogenicity of the strain was in many cases confirmed by animal inoculation. The expense involved prohibited the examination of all strains by this method. Random selection of cultures for the test was therefore made, but all strains which showed the slightest variation in cultural characteristics were included in the selection. Cultures from specimens of sputum were tested for virulence in forty-nine (34.5 per cent.) of 142 cases which had been reported as negative in the routine microscopical examination, and in sixty (15 per cent.) of 401 cases in which the direct film report was positive. The pathogenicity of positive cultures from specimens of pleural fluid, pus, urine, cerebrospinal fluid, and milk was thus confirmed. In no instance was a diagnosis based on the morphological and cultural characters of a strain proved erroneous on animal inoculation.

Results

Sputum.—As previously stated, the bulk of the material examined consisted of sputa from tuberculosis dispensaries and those received from practitioners for general bacteriological examination. In Table I are collected the results

TABLE I.—Results of Examination by Combined Direct Film and Cultural Methods of 3,306 Specimens for *B. tuberculosis*

Result		Specimen							Total
Film	Culture	Sputum	Pleural Fluid	Pus	Urine	C.S.F.	Milk	Faeces	
+	+	401	0	4	5	1	2	3	416 (12.5%)

+	-	9	0	4	0	0	2	0	15 (0.4%)
-	-	2,244	57	85	212	19	74	19	2,710 (82.1%)
		2,796	60	98	224	23	83	22	3,306 (100%)

obtained by the combined method. Of 2,796 such specimens 552 (19.7 per cent.) were reported positive by direct film, cultural, or combined examinations. Cultivation alone was successful in 543, or 98.3 per cent. of all positive results obtained. In the remaining nine specimens results obtained. In the remaining nine specimens results examination confirmed the presence of tubercle bacilli in direct films, but always in scanty numbers. The most significant finding was that only 410, or 74.3 per cent. of all positive results, were detected by the routine film examination. Repeated examination by separate observers confirmed the absence of tubercle bacilli in the original stained smears of the 25.7 per cent. of sputa later proved positive by culture. In such specimens the colonies appearing were often few in number, but not invariably so. Indeed, the rich growth which sometimes occurred was surprising in the face of a negative film report. As indicated in Table II, only five sputa were subjected to guinea-pig inoculation; all were negative in the triple test.

Pleural Fluid.—No specimen of pleural fluid was found positive by direct microscopical examination, but three were detected by culture. In these the number of colonies appearing on the Löwenstein medium were one, three,

C = culture; A = animal inoculation; + = positive; — = negative; d = delayed animal died before reading possible.

and four respectively, indicating the extreme paucity of the numbers of organisms present. Guinea-pig inoculation succeeded in one instance where direct film and cultural examination failed.

Pus.—Of the thirteen positive specimens of pus, mainly from lymphatic glands, direct film and cultivation failed in five and four respectively. As three of the negative cultural results were from old-standing lesions, the organisms seen in direct films were possibly degenerated or actually dead.

Urine.—Since this laboratory serves as a group laboratory for several municipal hospitals a large number of urines were received for general bacteriological examination. Animal inoculation being reserved for special cases, routine cultivation proved a useful accessory measure. Seven of the twelve positive cases being detected by this method. One specimen negative by both film and culture was positive on animal inoculation. Another specimen in which very few organisms were seen in direct films was positive on culture but negative on animal inoculation. In view of this surprising result the pathogenicity of the culture was confirmed by animal inoculation.

Cerebrospinal Fluid.—In the three specimens positive on cultivation only, the colonies appearing were in each instance few in number. Cultivation failed in one specimen positive by the animal test.

Milk.—The preculture treatment outlined above was not successful in eliminating all acid-fast saprophytes such as the timothy grass bacillus. These strains appeared rapidly on culture media, being clearly visible within two or three days, and were thus easily differentiated from strains of bovine tubercle bacilli, which were not apparent for an interval of eighteen days or more. Furthermore, growths of saprophytic strains were luxuriant as compared with the sparse dysgonic growth of the pathogen. Nine specimens positive on animal inoculation were reported on culture, while three positive cultural results were reported on animal inoculation. The pathogenicity of the latter strains was confirmed by animal inoculation.

Correlation of Bacteriological with Clinical Diagnosis

Although in most cases in human subjects from whom specimens had been received there was some clinical justification for the request that an examination for *B. tuberculosis* be carried out, the great increase in results obtained by the cultural method made it desirable to discover to what extent the bacteriological diagnosis agreed with the results of other methods of examination.

TREATMENT OF STREPTOCOCCAL EMPYEMA WITH INTRAPLEURAL SULPHANILAMIDE

EXPERIMENTAL STUDY IN RABBITS

BY

W. F. NICHOLSON, M.A., B.Ch., F.R.C.S.

Dickinson Travelling Research Scholar, University of
Manchester

(From the Department of Surgery, Washington University
School of Medicine, St. Louis, Missouri)

Methods

Rabbits were used in this work, for it is not difficult to infect them with a human strain of haemolytic streptococcus and pleural puncture is fairly simple in animals of this size. A haemolytic streptococcus isolated from a fatal case of septicaemia occurring in the hospital was passed successively through ten rabbits in order to increase its virulence for them. Equal doses of a broth culture of the organism recovered from the tenth rabbit were injected into the right pleural cavities of a series of rabbits of approximately equal weights. In one case the injection resulted in immediate death from haemorrhage, due to puncture of a blood vessel. The animals of the test series received regular doses of soluble prontosil by direct injection into the right pleural cavity, and an effort was made to remove a volume of fluid from the pleural cavity equal to the volume of prontosil to be injected, so that the intrapleural pressure was disturbed as little as possible. This was not always easy in practice. The drug was the 2.5 per cent. solution of prontosil. Hörlein (1935) has demonstrated that rabbits tolerate 50 c.cm. of this solution intravenously per kilogramme of body weight; but the largest dose used in these investigations was 10 c.cm., and this was found too large, for reasons suggested later. The control animals received the infecting dose of streptococci, but no treatment. Complete necropsies were performed, cultures being taken from the pleural cavity and the presence of prontosil in other organs observed.

Results

The first ten animals gave the results tabulated in Table I, which includes one other animal which died on being injected. Note the early deaths in the treated group, compared with the controls. In two cases in the test group there was a very marked shift of the mediastinum to the left, the right pleural cavity being filled with prontosil-coloured fluid. The pus in the test animals was thinner than in the controls, but this was probably due to their early death during the formative stage of the empyema. Although, as already stated, 10 c.cm. of 2.5 per cent. solution of prontosil is well within the tolerated dose for rabbits—these rabbits weighing on an average 1.2 kg—it became apparent that 10 c.cm. as a single intrapleural dose may cause considerable changes in intrapleural pressure; therefore in the next series of animals the dose was reduced.

In the second series (Table II) the four controls received streptococci into the pleural cavity; four test animals received 2 c.cm. of prontosil into the pleural cavity twenty-four hours after it had been infected, and subsequent doses of the drug as shown; four more were not infected, but prontosil alone was injected into the virgin pleural cavity. One animal in this last group died of septicaemia, probably having been infected by its cage-mates. The animals in this series survived long enough to develop thick pus in

the pleural cavity, and in only one case was there much of a mediastinal shift.

In the third series (Table III) four rabbits were inoculated with streptococci and prontosil at the same time; four were infected and the prontosil immediately given into the muscles; four were controls with no therapy. A decrease in virulence is shown in the last group.

In the fourth series (Table IV) two received prontosil alone, two streptococci. Four were inoculated with streptococci, and prontosil was given by the intramuscular route. Into the last four both streptococci and prontosil were injected simultaneously into the pleural cavity. The organism shows a marked decrease in virulence, most of the animals being killed after ten days, but the last group of four shows the greatest mortality, three of them dying of the disease with a positive pleural culture.

Two facts are apparent: first, that the animals which were given prontosil into the pleural cavity died earlier than those animals from which it was withheld; secondly, that the former more often had a positive culture returned from the swab of the pleural cavity. Some of the test animals died from effects due to changes in intrapleural pressure, but this did not account for all of them. Prontosil injected into the virgin pleural cavity did not appear to damage the tissues grossly, although it may have reduced local resistance in one case. Intramuscular injection of prontosil gave better results than its injection into the pleural cavity. No renal or hepatic lesions due to the prontosil were found.

Discussion

Sulphanilamide has so rapidly become a universal remedy that it is important to study its action in controlled experiments as much as possible. Most of this sort of work has been carried out in mice, the peritoneum being infected and the drug given by mouth or intramuscularly (Domagk, 1935; Levaditi and Vaisman, 1935; Colebrook and Kenny, 1936; Long and Bliss, 1937; Mellon, Gross, and Cooper, 1937). The action of sulphanilamide has also been studied *in vitro*, but experimental empyema does not appear to have been investigated. The increasing frequency of clinical cures of streptococcal empyema reported (Brown, 1937), where the method of treatment has been the direct injection of prontosil into the pleural cavity associated with daily aspiration of pus, makes it desirable to try a similar experiment in animals. Only the successes appear in clinical reports, and the cases rarely exceed two or three. As is well known, streptococcal infections are notoriously variable in virulence, and cases of streptococcal empyema sometimes resolved with simple aspiration long before prontosil was introduced. The cases reported in which prontosil had been used are those in which thick pus was present at the first aspiration. This in itself shows that the dangerous stage of the disease has already been passed, and the injection of prontosil may have had little to do with the subsequent thinning of the pus and disappearance of the organisms. The time when the drug is most indicated is, of course, at the onset of the infection, when the pneumonia is active but the empyema is only in its formative stage. It is then more logical to give the drug by mouth, intramuscularly, or intravenously. Good results are also obtained in the later stages of the empyema by the oral administration of the drug, according to several reporters (Mielnotte and Briquel, 1936). When this work was started it was hoped that perhaps prontosil might prove to be bacteriostatic when injected into the pleural cavity simultaneously with streptococci. If this had been proved its use in combating the virulent

culture. The x-ray appearances suggested a neoplasm of the lung. The patient died in hospital, but permission for a post-mortem examination was not obtained.

Discussion

The results of this investigation over a period of two years have justified a cultivation test in the routine examination for *B. tuberculosis*. The adoption of cultivation lengthens the examination considerably, and on this account careful choice should be made of the material subjected to the treatment. This entails the co-operation of clinicians, particularly in the case of laboratories dealing with large numbers of specimens from hospital sources. Much of the time and energy now expended on multiple routine examinations, often demanded without real justification, could be profitably devoted to a more prolonged investigation of a smaller number of likely cases.

The results of sputum examination were especially significant. Animal inoculations of all such specimens is rarely possible or even practicable, and in the absence of this test cultivation affords a very satisfactory substitute. In this series cultivation yielded an increase of 32.4 per cent. of positives over the direct film result. There is the possibility that multiple film examinations may have been more successful than the use of a single film, but it is extremely doubtful if the results secured by cultural methods could have been attained. That direct film examination is not sufficient has been indicated by Jamieson (1936), who found cultivation successful in 100 sputa from 100 known cases of phthisis, whereas repeated examinations of direct films were positive in but ninety-two cases. It is an additional advantage, moreover, in doubtful clinical cases, that the pathogenicity of the organism isolated from sputum can be confirmed if necessary. The routine procedure now adopted in this laboratory as regards sputum examinations is to report positive film results as before. In the case of negative results there is added a note that culture is being attempted and will be reported later if positive.

But the efficiency of the test cannot be gauged merely by the increased number of positive results which it yields. There must be confirmation of the bacteriological findings by other methods. That confirmation has been amply obtained, as the majority of the cases giving negative direct film but positive cultural results, and for which clinical data were available, were unquestionably infected subjects. All stages of infection have been detected in this way. In a very small number of subjects there was not, in the clinician's opinion, much ground for supporting the bacteriological diagnosis, but the possibility of this being correct could in no case be excluded. When one remembers the prevalence of subclinical infection as indicated by post-mortem examinations, tuberculin testing, and other methods, it is not surprising that cases of this nature will be discovered by the cultural method. But the delicacy of the test calls for great care in the taking of specimens for examination with tuberculous where the possibility of contamination with tuberculous secretions is present—as, for instance, the investigation of family contacts by the examination of sputa. Precautions must be made to ensure that only the subject's secretions and not those of a relative reach the specimen container. The method appears to be of value even in the early stages of infection, and may possibly be applied to detect an initial infection in childhood. Case 10 may prove to be an instance of this, as the child is now progressing satisfactorily. It may be stated here that there was no doubt that the growth was derived from the child's own secre-

tions and was of the human type. Shrewsbury has raised the point that the method may be applied to the detection of "carriers" of tubercle bacilli. While on account of the existing lack of information this possibility cannot be denied, it is more than likely that the so-called "carrier" is a person with a focus which defies clinical demonstration during life. Such cases can only be demonstrated by cultural or animal inoculation methods, so that the ultimate issue remains as before—namely, the possible detection of a hidden source of infection. One further point on which the method will furnish reliable information is the incidence of the two types of tubercle bacillus in human infections.

While not so striking on account of the smaller number dealt with, the usefulness of cultivation was also indicated in the examination of specimens other than sputa. At the present time, however, cultivation cannot entirely replace animal inoculation, particularly in specimens in which there is a possibility of the bovine type of organism existing in small numbers. Feldman (1934) after an investigation of similar nature came to the same conclusion. Animal inoculation cannot, however, be regarded as infallible, and in Table II appear four instances in which animal inoculation proved negative, whereas cultures from the same inoculum were positive. Examples of this type of result have been recorded by Woolley (1931). The results of animal inoculation and of cultivation (Table II) were the same in ninety-nine specimens and different in nineteen. Of these nineteen, animal inoculation was most frequently positive (thirteen), while cultivation was successful in four specimens which were negative in animals and two specimens in which inoculated animals died before a report was permissible. The optimum results, then, can only be secured in the investigation of such material by the utilization of both methods of examination.

Conclusions

1. Cultivation is a practicable measure in the routine examination for *B. tuberculosis*.
2. In a series of 3,306 specimens of all types, mainly sputa, the percentage of positives was 12.9 by direct film and 17.9 by the combined film and cultural examinations.
3. While animal inoculation is in most cases more reliable than cultivation, it is not invariably so.

It is with pleasure that I acknowledge the assistance and willing co-operation of the laboratory technical staff. With their help, and in particular that of Mr. R. K. Lister, such a large number of specimens could not have been handled. I am indebted to Professor T. J. Mackie for his interest in the work and the granting of various facilities. To all practitioners who supplied clinical data my thanks are due, for their information added a very real interest to the investigation.

streptococcus culture in 53 per cent. Seventeen animals treated with intrapleural prontosil survived an average of 5.7 days, the pleural fluid giving positive haemolytic streptococcus culture in 70 per cent. Eight animals treated with intramuscular prontosil survived an average of 7.8 days, with a positive haemolytic streptococcus culture in 37 per cent.

Summary

1. The direct effect of prontosil on streptococcal empyema has been studied in rabbits.
2. The treated animals died earlier than the controls.
3. No sterility of the empyema was produced.
4. The clinical value of these observations is discussed.

I have to thank Professor Everts A. Graham for providing facilities for the work, Professor J. J. Bronfenbrenner for helpful criticism, and the Winthrop Chemical Company for supplies of prontosil.

streptococcal empyema which sometimes complicates lobectomy would have been worth a clinical trial. But it appears to have no such action. This is in part explained by the recent work of Finklestone-Sayliss, Paine, and Patrick (1937), who have shown that sulphanilamide actually stimulates streptococci to multiply in the early stages of treatment, this effect being especially evident in young cultures. Later its bacteriostatic effect exerts itself. The danger of introducing prontosil into the pleural cavity may in part be due to this effect, in that the organisms multiply and reach the general circulation, whereas the drug is absorbed with increasing difficulty as the empyema develops. In the present state of our knowledge it seems

to be advisable to avoid the intrapleural injection of prontosil in cases of streptococcal empyema, but rather to give prontosil by mouth, or, if the drug is introduced by way of the pleural cavity, it should certainly be combined with the oral administration of prontosil. Naturally there is considerable difference between empyema in rabbit and that in man, but the dissimilarity can hardly be greater than the normal variation in virulence of human streptococcal infections, so that the results seen in the rabbit are not without their clinical interest.

Summarizing the results of the tables we find that fifteen animals, untreated, survived an average of 7.4 days each, and that the pleural fluid gave positive results in 10

A NOTE ON EPIDEMIC DROPSY

BY

J. V. LANDOR, M.D., M.R.C.P.

Physician, General Hospital, Singapore

AND

C. D. WILLIAMS, D.M., M.R.C.P.

Lady Medical Officer, General Hospital, Singapore

Several articles have appeared in the medical literature of the last few years referring to epidemic dropsy in India and other countries of the East, and associating outbreaks of the disease with the use of mustard oil for cooking purposes. The most recent we have seen is that by Lal and Roy (1937), who give a description of the disease and the various theories that have been put forward as to its causation, and who have come definitely to the conclusion that the ingestion of mustard oil is the cause. They admit that the majority of people who use mustard oil for cooking do not get the disease, and conclude that only certain forms of the oil sold commercially are toxic. In spite of several experiments they were unable to distinguish between harmless and harmful mustard oil. The Annual Report of Fiji for 1927, quoted by J. N. Leitch (1930), describes an outbreak there in which mustard oil certainly appears to have been the cause, and gives a detailed account of the symptomatology.

Three Recent Cases

Three cases which have been under our care recently at the General Hospital, Singapore, would seem to add corroborative evidence to these conclusions. The syndromes present suggested to us a common toxic origin, such as from some drug or plant taken internally. We consulted Professor R. B. Hawes of the Singapore College of Medicine on the matter, and he informed us that he had come across a similar syndrome in a few people some years previously, and that it had corresponded closely with mustard-oil poisoning or epidemic dropsy as described in the Fiji Annual Report mentioned above.

Case 1.—A male Bengali was admitted to hospital on June 17, 1937, complaining of general malaise. There was cardiac irregularity due to premature beats, microcytic anaemia, and oedema of the legs with the overlying skin of a dusky purplish colour. There was no fever while in hospital. He improved gradually with rest in bed and iron internally, and was discharged comparatively well on July 29, though still with slight oedema of the legs.

Case 2.—The wife of Case 1, also a Bengali, was admitted on June 24, 1937, complaining of pain and swelling in both legs and of one month's continued fever. Her temperature was 101° F. on admission, but this rapidly subsided in hospital. Her legs were oedematous from knee to ankle, tender, and painful, and were discoloured a peculiar mottled purplish red, rather more strikingly so than her husband's. There was a loud systolic cardiac murmur, heard best over the pulmonary area, as well as tick-tack rhythm. She was treated with iron for the anaemia, and with methylene blue (on account of a possible toxic element in mustard oil being a cyanide derivative.) She was discharged much improved on August 1, but with considerable anaemia still present.

Case 3.—The sister of Case 2 was admitted on June 27, 1937, seriously ill. Her legs were oedematous and intensely painful and tender; she also had had fever for one month, and this took some time to subside in hospital. The patient's legs were still more strikingly discoloured with purplish-red mottling. There was a dry irritating cough, and dry coarse crepitations all over both lungs. The heart was rapid and

slightly irregular, with tick-tack rhythm, a loud mitral systolic murmur, and an accentuated second sound at the pulmonary area. The urine was normal and the blood urea 36 mg. per 100 c.cm. Teleroentgenography of the heart showed enlargement, but when repeated at the end of treatment there was a considerable reduction in size. Microcytic anaemia was present, a little more severe than in the other two cases; the red blood cell count was 2,600,000 per c.mm., and the haemoglobin 44 per cent.: there was slight leucopenia. On July 15 she complained of blindness in one eye. On examination small scattered retinal haemorrhages were seen, one on the macula: these all cleared up before the patient was discharged on August 15, when the sight of both eyes was good. She was treated on the same lines as Case 2, with additional symptomatic treatment for the cough. On discharge there was still some anaemia and a pulse of rather poor volume, but the cardiac murmur had practically disappeared.

Conclusions and Commentary

These three patients had lived in the same house and shared the same meals; a fourth member of the family, a brother of the two girls who had previously lived with them, stated that he had also been affected in a mild form, and that he had suspected the food and had accordingly changed his abode. Mustard oil was used daily in the household cooking, and had been so used constantly in the past without ill effect. Some of the oil from the household was subjected to chemical analysis and also used for animal-feeding experiments; these were kindly undertaken by the Government analyst, Mr. M. Jamieson. The results were entirely negative, but it is doubtful whether the oil we obtained was from the same tin as that which had caused the illness: all the contents of that tin had probably been consumed before the patients came to hospital. On inquiry we found that a few other cases had occurred in the town, and we obtained other specimens of oil for examination, but none was found to be toxic to animals.

The syndromes of these patients fit in well with the usual description of epidemic dropsy, and differ from beriberi by the presence of the purplish-red mottling of the skin of the legs, the retinal haemorrhages, the fever, and the lung signs. The disease throughout the world appears only to have been observed among people who use mustard oil for cooking their food, and then merely in sporadic outbreaks; it is strange that the toxic element present has so far defied analysis.

We are indebted to the Director of Medical Services, Straits Settlements, for permission to publish.

G. de Flora and A. Crocetta (*Minerva med.*, December 2, 1937) state that though the hypotensive action of acetylcholine was demonstrated by Hunt and Taveau in 1915, the introduction of this drug into clinical medicine did not take place until 1928, when Villaret and Besançon were among the first to use it in various vascular disturbances of spastic origin, in scleroderma, and in lead poisoning with encouraging results. Their findings were confirmed by numerous Italian workers, but later investigators showed the extremely transient action of the drug, a dangerous diphasic stage, and an injurious influence on the heart. Subsequently, however, it was shown that the action of acetylcholine was counterbalanced by eserine, and the present authors found that the combination of acetylcholine with eserine made the hypotensive action of the former much more persistent without causing any dangerous diphasic stage.

PRIMARY CARCINOMAS OF THE STOMACH AND SIGMOID COLON OCCURRING SIMULTANEOUSLY

BY

RODNEY MAINGOT, F.R.C.S.

*Senior Surgeon to the Royal Waterloo Hospital and to the
Southend General Hospital*

Dr. Pemberton and Dr. Waugh of the Mayo Clinic, in the August, 1937, issue of *Surgery*, describe a case of a male physician, aged 57, who was admitted to their clinic suffering from a cancer of the sigmoid flexure of the colon. At operation primary growths were found to be present both in the colon and in the stomach. The tumour in the colon was excised after the manner described by Paul and Mikulicz, a subtotal resection of the stomach being undertaken some weeks later. Microscopically both growths were adenocarcinomas, and both were Grade 2. They write:

"Multiple primary carcinomas which affect the same individual have aroused the interest of the profession since the first reports of such lesions in 1869 by Billroth, although the frequency with which present-day pathologists report this finding is tending to make it almost commonplace. However, the finding clinically of two separate and distinct carcinomas appearing simultaneously in the sigmoid flexure and stomach is rare, and this, coupled with the fact that both lesions were amenable to surgical treatment, makes the report of the case unique. . . . The case . . . cited is, so far as we are aware, the only recorded instance of successful surgical removal of simultaneous independent carcinomas of the stomach and sigmoid flexure."

In view of these statements and also because I have had in my own practice recently a similar case, in which, however, it proved possible to excise at one single operation (partial colectomy and subtotal gastrectomy) both the primary growth in the sigmoid colon and the cancer of the stomach, I have considered it worth while to submit a record of the details of this case.

Case Report

A married woman aged 55 was admitted under my care at the Southend General Hospital on June 26, 1937, complaining of intermittent bouts of abdominal pain, loss of weight, and severe constipation. Some three months before her admission she stated that she had had several recurrent attacks of abdominal pain situated mainly centrally, but occasionally referred to the left side rather low down. The pain lasted only a few minutes, but was cramp-like and intractable. The attacks had no relation to food and did not appear to be relieved by medicines.

Approximately one month before admission she was seized with severe subumbilical colic and vomiting, which lasted for over six hours and then cleared up spontaneously. She had always been constipated, but this was becoming progressively worse, there being no history of attacks of alternating diarrhoea and constipation or of blood and slime in the motions. She had been gradually losing weight, and estimated that she had lost about two stone in three or four months. Her appetite was good and there were no symptoms of indigestion or other gastric disorder.

On examination she was thin and pale, the tongue was clean and moist, the abdomen was scaphoid rather than distended, and there was a palpable movable lump about two inches below and to the left of the umbilicus. A digital rectal examination as well as a sigmoidoscopic examination proved negative. A complete blood count showed that there was a

slight degree of secondary anaemia, and the barium enema revealed a small annular stricture at the beginning of the sigmoid colon.

On July 3, after a week's pre-operative preparation, the abdomen was explored (under spinal anaesthesia) through a left oblique Kocher incision which started at the tip of the tenth costal cartilage and proceeded vertically downwards towards the pubis, all the layers of the abdominal wall being divided in a line with the incision. A small freely movable growth was located in the gut at the point indicated by the barium enema. The abdomen was further explored to ascertain whether there were any metastases in the mesocolon, along the aorta, in the omentum, or in the liver. No enlarged glands could be detected in the mesocolon or elsewhere, but while a hand was being swept upwards into the epigastrium to palpate the right lobe of the liver an indurated mass was felt on the lesser curvature of the stomach; this was thought to be in all probability an early cancer of the stomach and not a secondary implant from the original growth in the colon. The descending and sigmoid colon was freely mobilized, and some twelve inches of gut (including the growth) exteriorized and resected by Paul's method.

The abdominal wound was closed as snugly as possible around the two short projecting portions of colon, and the clamps were left *in situ*, occluding the proximal and distal ends. This area of the operation was isolated with sterile towels, and as the resection of the colon had proved a simple matter and the patient's condition was highly satisfactory, after fresh sterile gowns, gloves, etc., had been donned, the epigastrium was immediately prepared for exploration.

Through a median vertical epigastric incision the stomach was examined and was found to contain an ulcerated area in the middle of the lesser curvature about one and a half inches long by two inches wide. On invaginating the stomach in the region of the greater curvature the ulcer could be felt to have a raised indurated edge, which was of stony consistency. There were a few shotty glands along the lesser curvature, but these did not appear to be malignant, nor was there any involvement of the visceral peritoneum of the stomach.

A subtotal gastrectomy, with removal of the great omentum, half of the first portion of the duodenum, practically the whole of the lesser curvature, and two-thirds of the greater curvature with all the adjacent lymph glands, was performed. The jejunum was brought over the transverse colon and the proximal portion anastomosed to the cut end of the stomach. After its top half had been closed, the proximal loop of the jejunum being applied to the reconstructed lesser curvature, and the distal loop to the greater curvature, after the manner suggested by Hoffmeister.

At the completion of this anastomosis it was found that the proximal jejunum took a rather short and graceful curve to the point of anastomosis, and it was therefore not considered necessary to perform an entero-anastomosis between the proximal and distal loops, a procedure which is now favoured by Balfour. The abdominal wound was closed in the usual way without drainage.

The patient made a splendid recovery, and was discharged on August 13 with the colostomy working well. She was readmitted on September 18, and a clamp was applied to the colonic spur on the Paul-Mikulicz stoma, while on September 29 the colostomy was closed under spinal anaesthesia. Shortly after this the bowels functioned naturally, and the patient's condition to-day leaves nothing to be desired.

The pathologist's report was adenocarcinoma of the sigmoid flexure without any involvement of the lymph nodes in the mesocolon which had been excised, and a microscopic section of the ulcer in the stomach showed adenocarcinoma undergoing colloid degeneration. Several glands which were adherent to the ulcerated region, particularly those adjacent to the ulcerated region on the lesser curvature, were examined microscopically, and were found to be normal in appearance.

bacteria, notably streptococci and less frequently Vincent's organisms, in any series of diphtheria patients. Pure cultures of diphtheria bacilli are obtained from carriers rather than from cases. Indeed, the associated organisms or secondary invaders may so overwhelm the cultures obtained from the most severe of infections that a second or third swab has to be taken to establish a bacteriological diagnosis the clinical counterpart of which has never for a moment been in doubt.

These three cases raise again the question of the Schick-positive carrier. Dudley (1923) says that so far as his experience goes the Schick-positive carrier is unknown. How, then, is a susceptible individual to obtain natural immunity except by an attack of the disease? That some do obtain it by another way is obvious, for how otherwise could 70 to 80 per cent. of adults have become insusceptible? Not all nor even the majority of them have had a clinical attack of diphtheria. Surely at one time in their history they must have been at least temporary carriers of small numbers of virulent diphtheria bacilli.

Immunization of the Schick-positive cases was carried out in six instances. Two doses of alum toxoid were used on four occasions and three doses of toxoid-antitoxin mixture on the other two occasions with complete success. It is strange to reflect that active immunity may be more readily produced by artificial than by natural means.

Summary and Conclusions

The results of Schick-testing a series of patients six or more weeks after an attack of diphtheria are reported. These results have suggested the following conclusions:

1. That after an attack of diphtheria, irrespective of its severity, about 10 per cent. of persons remain potentially susceptible.
2. That the chance of remaining susceptible is not diminished by delayed administration of serum.
3. That immunity is either developed early—that is, before the sixth week—or not at all.
4. That cases developing paralysis would appear generally to have acquired immunity.
5. That cases which do not develop a natural immunity as the result of infection respond satisfactorily to active artificial immunization.

In the twelve months September 30, 1936, to September 30, 1937, eighty-seven students received training in the medical side of missionary work abroad at Livingstone College. The annual report contains numerous personal tributes to the practical value of this training, which is available for all Christian missionary students without any denominational discrimination. There was a small financial deficit on the year's working, due in large measure to a fall in the amount received from the students' fees. The number of students, it is mentioned, has slightly increased, but the majority in that year only came for short periods. The report contains also the speech delivered at the Commemoration Day meeting in June, 1937, by Mr. W. A. Cadbury, relating to his work in Northern India. The volume of testimonies to the usefulness of the curriculum at Livingstone College shows how missionaries thus trained can be of the greatest value in parts of the world where ordinary medical assistance is scanty.

Clinical Memoranda

"Mixed Tumour" of the Lip: Report of Two Cases

After reading Mr. R. Pilcher's article in the *British Medical Journal* of May 8, 1937 (p. 967), I feel that the following two similar cases of "mixed tumour" of the lip are worth recording. Case II came to my notice a few weeks following the appearance of Mr. Pilcher's article; the other was encountered in 1935.

CASE I

A Chinese woman, aged 24, had had a swelling on the right side of the lip for four years. The tumour was oval, about the size of a walnut, and quite firm.

Histologically the tumour consisted of a fibrous tissue stroma in which were strands of epithelial cells, most of them in alveolar formation, and some appeared to be lining the lymph spaces. Small dark epithelial cells with hyperchromatic nuclei arranged in solid masses were also in evidence. In various areas mucoid and osteoid tissue as well as hyaline material were seen. Lymphocytic infiltration was pronounced in various parts of the tumour.

CASE II

This patient, a Chinese woman aged 36, had had a painless slow-growing swelling on the upper lip for thirteen and a half years. There was no history of trauma, the swelling having first started as a small reddish nodule, growing very gradually. On examination it was found to be hard, pedunculated, and freely movable. It was covered by a tense skin, and several prominent vessels could be seen on its surface. Its under-surface was continuous with the mucous membrane of the lip. The removal of the tumour was followed by a skin graft.

The specimen was oval in shape and about 3 by 2.5 cm. It was firm, encapsulated, and covered by skin. On section it showed a white and opaque smooth surface, containing several small yellowish areas.

The histological report was as follows: "Section shows acini and solid clumps of epithelial cells lying in a fibrous connective-tissue stroma, which in places appears myxomatous. The acini are lined with low cubical or flattened epithelium. Their contents appear pink-staining and homogeneous. Some of the acini are dilated and cystic. The solid masses, with their closely packed cells and a tendency to form cell nests in the centre, present a striking resemblance to squamous epithelium. Distributed in the stroma are seen cartilage-like areas and foci of lymphocytic infiltration."

These two cases were encountered in the course of the routine examination of biopsy material submitted by the University Surgical Clinic. Reports of similar cases in other parts of China are lacking.

I am much indebted to Professor K. H. Digby for the clinical reports.

K. T. LOKE, M.B., B.S.

Department of Pathology, University of Hong Kong.

A Case of "Mixed Tumour" of the Upper Lip

I was greatly interested in the case of "mixed tumour" of the lip reported by Mr. Robin Pilcher in your issue for May 8, 1937. By a coincidence it so happened that on the day on which I read his report an almost exactly similar case was in my wards awaiting operation.

SCHICK RELAPSE AFTER DIPHTHERIA

BY

F. PYGOTT, M.B., D.P.H.

Late Assistant Resident Medical Officer, Little Bromwich Hospital

Second attacks of most infectious diseases are somewhat rare. A history of a previous infection in a child suffering from a typical attack of measles raises grave doubt as to the correctness of the earlier diagnosis. Similarly, infection with chicken-pox, rubella, variola, mumps, and the organisms of the enteric group confers an immunity which, if not lifelong, is of many years' duration. Even vaccinia confers sufficient immunity to exert some protective effect for a period as long as the average expectation of life at birth (Hanna, 1913).

The position with regard to scarlet fever and diphtheria is not nearly so clear-cut. Second attacks of both diseases undoubtedly occur. Rolleston (1929) found that of 3,000 cases of diphtheria forty (1.3 per cent.) had relapses and sixty-seven (2.2 per cent.) gave a history of a previous attack. Fortunately we have in the Dick and Schick tests yard-sticks which may be used as a measure of the relative immunity conferred by the primary infection. While we cannot say that a Dick-negative person is unable to contract scarlet fever or that a Schick-negative person is unable to contract diphtheria, we know that they are much less liable to do so than a corresponding Dick-positive or Schick-positive person. We know, too, that even if they are so unfortunate as to contract either disease their chances of rapid uncomplicated recovery are very much greater than those of the Dick-positive or Schick-positive person.

The object of this investigation was to form some idea of the frequency with which cases reverted to Schick-positiveness six or more weeks after an attack of diphtheria. All the patients received serum, and so they must at some time during their illness have been Schick-negative either actively, as a result of their own antitoxin, or passively, as the result of the antitoxin administered. Schick (1911) himself noted the rapid disappearance of antitoxin after an attack in some cases. Dudley (1923) reported that of fifty cases of clinical diphtheria occurring at the Royal Naval School, Greenwich, eight were still Schick-positive or gave a positive combined reaction three to six months after an attack. He did not encounter a second case in any boy who had had a previous attack, in spite of prolonged exposure to infection under ideal circumstances for its spread. He deduced, therefore, that "one attack of diphtheria confers immunity in the vast majority of instances, even if the Schick reaction remains positive."

However true this statement may be, the practitioner in charge of a Schick-positive case of clinical diphtheria cannot excuse a delay in giving serum even though he may be sure that the patient has had a previous attack. His duty is too plain to be avoided. The theories of sub-immunity developed by Glenny (1925), however accurate they may be in the mass, cannot be relied upon in any individual case, for clearly if a patient's circulating antitoxin is less than the amount required to render him Schick-negative we have no ready method of finding out whether he is only just susceptible or entirely unprotected. Delay may do no harm or may be dangerous, none can say which. Treatment on these lines becomes a gamble.

The Investigation

Eighty-seven entirely unselected cases of diphtheria were Schick-tested six or more weeks after a definite clinical attack. The diagnosis was confirmed bacteriologically in every case. Nine gave a positive reaction. They were retested with the same result. Seventy-one were female, of whom seven were positive, and sixteen were males, of whom two were positive. The age distribution was as follows:

	0-2 years	2-5 years	5-10 years	10 years or over
Number of cases ..	1	17	48	21
Positive reactors ..	—	1	6	2

It was thought that perhaps the day of disease or admission, which was also the day on which serum was given, might be in some way connected with the Schick relapse. The cases were grouped:

	Day of admission		
	1st and 2nd	3rd to 5th	6th day and on
Number admitted ..	20	47	20
Number positive ..	3	4	2

They were also grouped according to the localization of the disease:

	Faucial	Nasal	Combined Faucial and Nasal
Number of cases ..	51	10	26
Positive reactors ..	7	—	2

and again according to the dosage of serum employed:

	Dose in thousands of units		
	2-8	12-32	12-215
Number of cases ..	50	22	15
Positive reactors ..	5	3	1

The Schick test was performed between the sixth and twelfth weeks in seventy-one cases, seven of these being positive, and between the twelfth and twenty-fourth weeks in sixteen cases, with two positive results. Paralysis occurred in thirty-one cases. Only one of these was later found to be Schick-positive. No paralysis occurred in the other fifty-six cases, and eight of these were later Schick-positive.

The Schick-Positive Carrier

One Schick-positive patient had had a previous attack twelve months before. Three had virulent diphtheria bacilli in their throats at the time they were Schick-positive yet none had any clinical evidence of the disease. One of the three, who had been a chronic carrier for nearly four months, developed a second attack in the twenty-fourth week. She received 2,000 units of antitoxin.

The criteria adopted for the diagnosis of a second attack were the presence of a clinically diphtheritic lesion in the nose or throat, a Schick-positive reaction in the patient, and the bacteriological finding of virulent diphtheria bacilli in the swabs taken from the lesion. The fact that organisms were found in the cultures was not held to affect the diagnosis, for more often than not it is difficult to find in association with the causative bacilli

neurologist this method may seem of doubtful orthodoxy, and he will no doubt consider the expositions in many cases superficial and even in some respects misleading; yet even he, when asked to give a clinical lecture to students or masseuses, or some such not too critical audience, on headache or involuntary movements or such-like topic, will turn with gratitude to Purves-Stewart to make sure that he has adequately covered the ground.

Several of the chapters have been rewritten in this edition to bring them up to date without, as the author himself remarks, altering the original conception and plan of his subject. Nor, fortunately, has this rearrangement added to the length of the book, already extended to over 800 pages. To try to give any conception of which parts of this edition are new would involve more than can be compassed in a review, and it may be more useful to remind old readers of its scope and introduce new readers to its usefulness. After a short review of the physiological anatomy of the nervous system and methods of case-taking, such symptoms as delirium and coma are dealt with, then involuntary movements from convulsions to rigors are described. There is a useful summary of aphasia and disorders of articulation, followed by a discussion of the diagnostic significance of lesions of the cranial nerves. This leads to chapters on the differential diagnosis of pain and abnormalities of sensation, which are particularly useful to the practitioner. Paralysis of all types are dealt with, and a useful clinical description is given of incoordinations and peculiarities of postures and gait. Trophoneuroses of endocrine origin are dealt with, as are affections of the vegetative nervous system. There are useful sections on the significance of reflexes, electro-diagnosis and prognosis, and cerebrospinal fluid findings. A chapter on psychoneuroses is inserted, and while this will not please all modern psychologists it contains many good clinical descriptions, especially of hysterical syndromes. Disorders of sleep are discussed briefly, and finally there is a long chapter on intracranial tumours, which is founded on the author's book on this subject.

The volume is well produced, with copious case histories and good illustrations, and is written in the easy readable style which we expect from the author. We have every expectation that the present edition will prove as useful and popular as its predecessors.

YEARBOOK OF RADIOLOGY

The 1937 Year Book of Radiology. Edited by Charles A. Waters, M.D., Whitman B. Firor, M.D., and Ira J. Kaplan, B.Sc., M.D. (Pp. 503; 550 figures. 4.50 dols. or 19s.; postage inland 7d., abroad 1s. 3d.). Chicago: The Year Book Publishers, Inc.; London: H. K. Lewis and Co. Ltd. 1937.

This yearbook maintains the high standard of its predecessors. The first of the series appeared in 1932, and the form of the book has not altered much since then. It is, as usual, in two parts. Part I, Radiologic Diagnosis; Part II, Radiotherapeutics. The international literature of the previous year has been carefully searched, and almost all that is new is commented upon, with suitable illustrations and references. Attention might be specially drawn to the injections of opaque substances and to the effect of drugs on the gastro-intestinal and genito-urinary tracts.

An excellent article by Twining of Manchester on "Tomography by Means of a Simple Attachment to the Potter-Bucky Couch" is referred to and a good description of the apparatus is given, with diagrams and its method of use. There is a useful chapter on the teaching and principles of practice, which includes long extracts

from a paper by Kornblum and Tumen on "What the Radiologist Should Know about Clinical Pathology." Many instructive cases of rare pathological conditions of the gastro-intestinal system are recorded, and extracts from a paper by Ritvo on drugs as an aid in roentgen examination of the gastro-intestinal tract should prove of great interest.

Under radiotherapeutics all the various methods of x-ray and radium treatment are dealt with, and one chapter is devoted to radiation physics. The work of Eve and Grimmer of London on radium beam therapy is referred to, and the difficulty of obtaining from radium a large depth dose, on account of the short distance at which it must be used, is discussed, and beam therapy is compared with high-voltage x rays. Low-voltage near-distance x-ray therapy is described, and Chaoul's work in making this method applicable to lesions of internal organs is outlined. The latest "super-voltage" therapy—that is, kilovoltages of 1,000 and upwards—is discussed, but the author is of opinion that notwithstanding its theoretical advantages it has yet to be proved that it is of enough practical value to warrant the enormous expenditure required for its installation. The reports from various clinics where this particular form of therapy is employed still leave doubts as to its value.

A short chapter on radiation injuries is of great service and should be read by all radiotherapists. There is an excellent summary of a paper on "X-Ray and Radium Injuries of the Skin and Mucous Membrane" by M. C. Tod of Edinburgh. In this the danger of overdosage, with the final production of x-ray cancer some years later, is discussed. The book is well illustrated throughout and there is an excellent index.

MENTAL HOSPITAL ADMINISTRATION

Administrative Psychiatry. By William A. Bryan, M.D. (Pp. 349. 15s. net.) London: George Allen and Unwin Ltd. 1937.

It was the reviewer's good fortune to meet Dr. William Bryan a few years ago and to spend a day at the Worcester State Hospital. From reading his book one might be inclined to picture Utopian buildings and equipment and to congratulate him on his good luck to preside over them. In actual fact the bricks and mortar are neither better nor worse than in the average mental hospital here or in America, but the administrative philosophy and leadership have produced a spirit of enthusiasm and co-operation which has made Worcester one of the most famous mental hospitals in America.

This book explains the philosophy of "participative democracy" upon which the hospital is run, and in addition gives a great many details of administrative technique. Dr. Bryan has an exceptionally high ideal of what a mental hospital should be and for what it should stand in the life of the community. He would no doubt be dubbed an impractical visionary had not most of his ideas become current practice during his many years of superintendence at Worcester.

Such a frank and detailed book, covering as it does the whole field of hospital organization and administration (there are chapters on building a staff, on the nursing problem, teaching, co-ordinated research, "public relations," etc.), must inevitably contain many debatable ideas—for instance, the wisdom of the practice of periodic rating for efficiency of the nursing staff by a medical committee. But Dr. Bryan points out that psychiatrists have not hesitated to "sell" their psychological theories of management to the industrial world, though in the

CASE-RECORD

The patient was a Hindu lady, aged 25, who came to hospital complaining of obstruction to breathing through her right nostril. This was found to be due to a swelling the size of a walnut in the substance of the right upper lip. She stated that the swelling had started without cause three years previously, and that it had grown slowly, causing no disability until a few months before, when the obstructed breathing had come on.

The tumour was firm, coarsely lobulated on the surface, quite free from attachment to skin and mucous membrane, of even consistency with a definite edge, freely mobile, not translucent, and not tender. An out-patient diagnosis of a "submucous retention cyst" was obviously wrong, and was altered to that of a "mixed tumour" as soon as the case was seen. The tumour was removed through an incision in the mucous membrane of the lip, and shelled out with perfect ease. Convalescence was normal. The pathological report, for which I am indebted to Dr. P. Ramachandra Rao, professor of pathology in the Vizagapatam Medical College, is as follows:

PATHOLOGICAL REPORT

"Naked-eye Appearance.—The tumour is an irregularly oval, greyish-white, slightly bosselated, encapsulated, fairly firm mass about the size of a marble ($1\frac{1}{2} \times 1\frac{1}{2}$ cm.). The greyish-white cut surface is slightly bulging, faintly lobulated at the periphery, and shows an irregular slightly depressed white fibrous area at the centre. The bulging periphery has a mucoid adenomatous appearance. No cysts are, however, distinguishable even with the magnifying glass.

"Microscopical Appearance.—The section shows small spindle-shaped cells with oval plump nuclei containing one or two nucleoli and with scanty cytoplasm, arranged closely in sheets or branching columns or in the form of alveolar networks. In some places the cells form a cluster of branching papillae with very delicate hyaline connective-tissue cores. In others, especially about the cicatricial centre, rounded masses of these cells undergoing hyaline change have formed typical epithelial pearls. In still other areas tubular spaces of varying size, but principally of microscopic dimensions, with homogeneous hyaline contents and lined by cuboidal epithelium in which the nuclei lie near the base, are seen. Some of the tubules have a double lining of the epithelial cells—the distal layer being more columnar in shape. The stroma is formed principally by a mucoid embryonal type of connective tissue, which contains lobules of fatty tissue in places. The centre, however, shows dense hyaline connective tissue with septa radiating from it to the periphery between the epithelial masses giving rise to the lobulated appearance. Cartilage is not in evidence. The stroma, however, shows a fair amount of elastic tissue, particularly in the centre. The vessels are thin-walled and scanty.

"The tumour belongs to the group of 'mixed tumours' of the salivary gland, and may more appropriately be called epithelioma adenoides cysticum."

MAJOR F. M. COLLINS, M.B., F.R.C.S.,

Medical College, Principal and Professor of Surgery.
Vizagapatam.

An International Congress on Rheumatic Diseases will be held at Bath, March 31 to April 3, to celebrate the bicentenary of the Bath Royal National Hospital for Rheumatic Diseases. Lord Horder will deliver the presidential address. In a discussion on "Gout and Chronic Rheumatism of Metabolic Origin" Sir Walter Langdon-Brown and Dr. Mathieu-Pierre Weil will be among the opening speakers. Other papers will be read, and the programme also includes a demonstration of cases at the hospital, a mayoral reception and dance, a banquet at the Guildhall, a tour of the baths, and excursions to places of interest in the neighbourhood. Particulars can be obtained from the joint honorary secretary, Dr. G. D. Kersley, 6, The Circus, Bath.

Reviews

APPENDICITIS

Appendicitis. A Clinical Study. By W. H. Bowen, M.S., F.R.C.S. With an introduction by Sir Arthur Hurst, D.M., F.R.C.P. (Pp. 202, 7s. 6d. net.) Cambridge: At the University Press, 1937.

Mr. W. H. Bowen's monograph on appendicitis is a clinical study, and in his preface the author states that his aim is to give the student and practitioner a broad outline of the common varieties of disease of the appendix. For this reason rarer manifestations such as actinomycotic, tuberculous, and malignant disease have been excluded. Aetiology, diagnosis, complications, prognosis, and treatment are discussed in a work of some two hundred pages in which illustrative cases are also recorded. Chapter on obstructive appendicitis, appendicitis with pregnancy, and the controversial subject of chronic appendicitis are of particular interest. Mr. Bowen favours the pararectal (Battle's incision) approach in most cases, but advises the muscle-splitting incision when the disease complicates pregnancy. The discussion on when to carry out expectant treatment is clearly and logically put, and there can be no disagreement with the conclusion that unless indications for delay are definite and unmistakable the safest and wisest course is immediate operation.

In an introduction Sir Arthur Hurst writes that physicians will welcome a definite statement as to the indications for surgery in chronic appendicitis, with a very convincing analysis of a series of cases in which there has been no recurrence of symptoms over a period of several years following operation. There will be general agreement with the statement that "a man who instead of insisting on a preliminary thorough examination is ready to say, 'Let us have a look inside—we can always remove the appendix,' should have gone into business instead of becoming a surgeon." This work should have a particularly wide appeal, for there is much in it to interest radiologists and physicians as well as surgeons and general practitioners. It is a really excellent account of the aetiology, diagnosis, and treatment of the various types of appendicitis, and a most welcome contribution to our knowledge of this very frequent condition, which even to-day has a regrettably appreciable mortality.

NEUROLOGICAL DIAGNOSIS

The Diagnosis of Nervous Diseases. By Sir James Purves-Stewart, K.C.M.G., C.B., M.D., F.R.C.P. Eighth edition. (Pp. 842; 337 figures. 35s. net.) London: F. Arnold and Co. 1937.

It is a remarkable thing for a book on diseases of the nervous system to reach an eighth edition in a period of just over twenty years. That it should do so is a proof of its widespread popularity and utility. It is not uncommon for the general practitioner to complain that the diseases of the nervous system are so complex and confusing that he can make neither head nor tail of them, and yet he can hardly go through one day's work without being met with signs or symptoms associated with the nervous system. Pain, paralysis, or peculiarity of conduct are all daily problems which are difficult to elucidate from the systematic textbook, and what he wants is to be able to look up accounts of these various types of cases which will guide him in assessing the probable cause. This is just what "Purves-Stewart" gives him, and it doubt accounts for the book's success. To the end

character with a rigid distorted personality, the sex deviate, and the criminal. Stress is laid upon the influence of the neurotic parent in building up the neurotic child, and a plea is entered to let the child grow up instead of overmuch trying to bring him up. There is a brief description of the sort of treatment given by the psychiatrist, and the book begins with a description of a few mal-adjusted persons and ends with that of a few who have grown up in emotional health. There are a very large number of books such as this, and though Dr. Adamson's is clearly enough written we doubt if it will bring very much more understanding to the laity than its predecessors.

General Selection from the Works of Sigmund Freud, by JOHN RICKMAN (Selwyn and Blount, 5s.), is the first of a series of psycho-analytic epitomes which are designed to give the reader an outline of the development of theory and not an exposition of case histories or a short cut to instruction in treatment by psycho-analysis. The arrangement is in large measure historical, tracing the development of Freud's thought and the modifications he has made in his original theory. The lectures in which he first enunciated his new conceptions are quoted fairly fully, then shorter selections are given dealing with special points such as the pleasure-pain reality concept, the unconscious, negation, the vicissitudes of instincts, repression, character types, narcissism, and depression. Next the further developments are quoted starting with the concepts of beyond the pleasure principle and suicide, the Ego, the Superego and the Id, and the later work on anxiety. Finally there is a bibliography and glossary. The chief attraction of this book will be for those already acquainted with the work of Freud who wish to dip back and remind themselves of certain points without having recourse to each separate volume from the library. It may stimulate interest in the neophyte, but unless he is prepared to go back to the original and study the questions in full this book will not be of much use to him.

We have received a copy of the *Proceedings of the First Congress of Internal Medicine* held by the Argentine Medical Association at Buenos Aires under the presidency of Dr. Rodolfo A. Ayherabide in September, October, and November, 1936. Two subjects were chosen for discussion—namely, bronchiectasis from September 28 to October 2, and chronic appendicitis from November 23 to 27. The work is a richly documented and liberally illustrated volume of 654 pages, which can be strongly recommended to readers of Spanish interested in bronchiectasis and appendicitis.

The Nurse's Pocket Encyclopaedia, Diary, and Guide for 1938 (Faber and Faber Ltd.; in ordinary binding 1s. 6d., in superior binding with a pencil 2s.) takes the place of *The Nursing Mirror Pocket Encyclopaedia and Diary*. It is a useful little book containing information on all branches of nursing, and including a section on drugs, a directory of nursing institutions, and many recipes with which to tempt back the convalescent patient's appetite. It has been rather erratically revised, however. A note on prontosil contrasts strangely with a celery-seed recipe for rheumatism. The suggestion that the sterilization of raw catgut is simple is dangerous, and many of the splints and instruments depicted have not even a historical significance.

Dr. VALLERY-RADOT has done a large amount of work on anaphylaxis, particularly in rabbits, and, together with Drs. MAURIC and HOLTZER, he has now produced *L'Anaphylaxie Expérimentale et Humaine* (Paris, Masson et Cie, 36 fr.). The first part of the book deals mainly with the authors' experiments on anaphylaxis in rabbits. A remarkable observation is that rabbits cannot be sensitized passively by the ingestion of serum of sensitized rabbits. Striking photographs showing vasoconstriction

during shock, as revealed by arteriography, are included. Anaphylactic shock as seen in guinea-pigs is dismissed in three pages. Much important work done by other investigators is not mentioned. The second part of the book is concerned almost entirely with allergy in man, particularly with the detection and treatment of the allergic state. The authors conclude that the only methods of any value for the detection of the condition are the skin reaction and the Prausnitz-Küstner reaction.

It remains to be seen whether political changes in Germany will react to the permanent detriment of medical research in that country. In certain spheres its contributions have lately been few, and among these is cancer research. It appears to be the object of *Neuere Ergebnisse auf dem Gebiete der Krebskrankheiten*, edited by Dr. C. ADAM and Professor R. AULER (Leipzig, S. Hirzel, RM. 12), to acquaint the medical public of Germany with the present position of cancer research, both clinical and experimental. Its forty-six chapters are devoted, some to the technique of diagnosis and treatment of cancer in different organs, and some to the experimental study of the disease and other aspects concerned with its aetiology. The individual subjects in the latter category include chemical carcinogenesis, viruses, tumour metabolism, racial and other inherent susceptibility, industrial cancer, and methods of serological diagnosis. This compendium will serve its general purpose, but the serious inquirer will find the account of some of these numerous subjects far from complete, and will regret the frequent absence or paucity of lists of references.

Preparations and Appliances

X-RAY MATERIALS AND ACCESSORIES

The medical and scientific department of Kodak Limited have sent their latest catalogue of x-ray materials and accessories. What chiefly strikes us is the bewildering number of sizes to which x-ray films and papers are cut. The film is supplied on four different types of base and in seventeen sizes denominated by inches and in six others denominated by centimetres. Dental x-ray film is issued in nineteen kinds, varying in size and coating. The sizes of x-ray papers are almost as varied as those of films, running from a little larger than a lantern slide up to a sheet of 40 by 50 centimetres. The number of accessories which are convenient if not essential to the x-ray department continues to increase, and the catalogue gives particulars of cassettes, exposure holders, intensifying screens, negative markers, developing tank outfits, hangers, thermometers, illuminators, and, finally, serial folders, in which are placed six or a dozen barium-meal half-plate reduced prints, complete with report sheet and envelope. A feature is made of an improved type of x-ray reduction camera, offering a simple means of making reductions—prints, transparencies, or lantern slides—from negatives up to a size of 17 by 14 in., without visual focusing, automatic focusing scales being provided.

MALTED MILK WITH VITAMIN D

Cow and Gate (vitamin D) malted milk (Cow and Gate Ltd., Guildford, Surrey) is a milk powder which is fortified with a natural vitamin D (cod-liver oil) concentrate. It is recommended as a well-balanced food-drink for persons of all ages.

OSTOALCALCIUM TABLETS

Glaxo Laboratories Ltd. (Greenford, Middlesex) have now improved both the flavour and the friability of these tablets, while substantially increasing their calcium content. Two and a half grains of calcium phosphate have been added to the original formula (7½ grains calcium sodium lactate and 500 international units of vitamin D). Thus each ostoalcalcium tablet now supplies 1½ g. (0.1 gramme) of metallic calcium. The price is unchanged.

psychiatric hospitals these principles have often escaped our attention. He believes that the best way to build up a loyal and enthusiastic personnel is by developing a true democracy in management. Dr. Bryan has written a most useful and stimulating book.

REGIONAL ANATOMY IN BRIEF

Short Manual of Regional Anatomy. Written for the Medical Student as an Aid to a Rapid Revision of the Whole Subject. By J. A. Keen, M.B.Lond., F.R.C.S.Eng. (Pp. 167; 76 figures. 5s. net.) London, New York, Toronto: Longmans, Green and Co. 1937.

This small book has been written for the medical student as an "aid to rapid revision of the whole subject." It differs considerably from other works with a similar purpose. Keen's *Manual* is an attempt to combine the purely verbal descriptions of certain well-known anatomical revision books with the pictorial or diagrammatic method. The mental exercise of remembering a written description is thus assisted by a visual concept. The book is well written, terse, and to the point, and although some parts are more fully dealt with than others it does cover most of the matter that a student is required to know for the ordinary examinations, and should prove specially useful to a type of student who in his endeavours to be thorough in the study of one particular region—for example, the central nervous system—finds shortly before an examination that he has no time for revision of other important parts. But it is obvious that however skilful the author may be he cannot compress the whole subject of human anatomy within the limit of a small book such as the one we are considering. A surprising amount of information is, however, contained in Keen's *Manual*, and we can recommend it for use in the way which has been indicated—namely, that of revision.

We have little in the way of constructive criticism to offer. Certain of the illustrations, however, are, as the author himself admits, "very diagrammatic"—for example, Fig. 74 (p. 140) and Fig. 75 (p. 142). These might be improved with benefit both from the artistic and educational standpoints. There are many students, however, who will not worry themselves about aesthetic considerations so long as the book will help them to get through their examinations, and it is for these that it is intended.

BACTERIOLOGICAL DIAGNOSIS OF TUBERCULOSIS

Diagnostic Bactériologique de la Tuberculose. By A. Saenz and L. Costil. (Pp. 240. 40 fr.) Paris: Masson et Cie.

Rapid strides have been made in the last few years in the bacteriological diagnosis of tuberculosis; but the clinician is apt to be confused by the large amount of published work, not seldom contradictory. A concise authoritative statement on the relative value of the different methods was overdue. This is now provided in the book by Drs. Saenz and Costil, published from the Pasteur Institute. The authors deal purely with the bacteriological aspects, but their findings, based on extensive personal experience, are put forward briefly and clearly. There should be no difficulty in applying their conclusions to clinical work.

A historical sketch of the culture of the tubercle bacillus is followed by a brief description of the various culture media, and the results of studies of their comparative value and of the relative sensitiveness of the methods of culture and guinea-pig inoculation. The

authors describe the method of culture they have found most satisfactory, and give the experimental work on which this opinion is based. A chapter is devoted to the precautions that must be taken in interpreting results obtained by the direct method, the culture method, and guinea-pig inoculation; and a simple method of determining the type of the bacillus is described. The bacteriological diagnosis of tuberculous materials—sputum, pleural effusion, cerebrospinal fluid, urine, gastric lavage fluid, and specimens removed at necropsy—is discussed in detail. The last section, which forms a third of the volume, is devoted to the authors' investigations on tuberculous bacillaemia. The work was partly carried out in connexion with the inquiry of the Health Organization of the League of Nations into the claims made by Loewenstein.

This is a most useful publication, though we should like to make one criticism. A summary or conclusions at the end of each section would have been of great help to the busy practitioner. This, however, could easily be corrected in a future edition. The book fills a gap, and can be unhesitatingly recommended to all tuberculous workers.

Notes on Books

We have received a copy of the second volume of the *Transactions of the Institute of British Surgical Technicians*, which contains among other items of interest, papers on "Hearing and Hearing Aids," by Mr. Terence E. Cawthorne, on "Modern Operation Theatre Technique," by Mr. F. F. Rundle, and on "Sterilization of Surgical Ligatures," by Sir Weldon Dalrymple-Champagne. There is also an interesting paper by Mr. H. C. Hopwood on "Stainless Steel." The price of the volume is 30s. net.

The third volume of the forty-seventh series of *International Clinics* consists of seven sections devoted respectively to medical clinics at the Johns Hopkins Hospital, tuberculosis and syphilis, diseases of the lungs, cardiovascular disease, endocrinology, diseases of metabolism, and diseases of joints. The publishers are J. B. Lippincott and Co., and the price is 50s. a set of four volumes.

The last fasciculus of Vol. iv of the *Traité de Colloïdogie* by Professor W. KOPACZEWSKI deals with narcosis (Paris: Gauthier-Villars, 35 fr.). The author has collected extensive data concerning the physical, chemical properties of narcotics and the action of narcotics on the hydration of proteins. It is nearly 20 years ago that Overton and Meyer showed the remarkable parallel between the lipid solubility of narcotics and their biological action. Since then the relation between the physicochemical properties and the biological action of narcotics has been the subject of intensive research, and an enormous mass of data has been accumulated. The general result has been to show a remarkable series of striking parallels. A large number of alternative theories have been evolved regarding the physicochemical nature of narcotic action, but no single one has found general acceptance. The monograph under review is an account of certain of these theories, but its length (200 pages) is inadequate to permit an exhaustive treatment of this very wide problem.

So You're Going to a Psychiatrist? by Dr. FETTER and ADAMSON (London: Sir Isaac Pitman and Sons, 12s. 6d.) is one more attempt to explain modern psychiatry to the lay public. The trend of modern medical psychology is explained along Freudian psycho-analytic lines. The types of "patient" are described—the neurotic, the psychotic, the deviations from normal in his behaviour, etc.

is absent, or that direct film examination of sputum is negative, can no longer be justified.

The cultural method is thus of far-reaching importance in treatment of pulmonary tuberculosis and prevention of all forms of tuberculosis. Its universal practice would, moreover, probably influence current statistical notions, the present classification into "sputum-positive" and "sputum-negative" patients being based on vaguely defined and bacteriologically unreliable terms. The method can no longer be regarded as an investigational luxury or as a Continental fad, and facilities for its practice in association with the work of every tuberculosis dispensary and institution should form an essential item in the control of tuberculosis.

MODERN VIEWS ON PELLAGRA

Stannus¹ has recently shown that pellagra, which is endemic in Spain, Italy, Rumania, Egypt, and the southern States of the U.S.A., also occurs in Africa and in the tropical parts of Asia, America, and Australia, notably in prisons, asylums; and similar institutions. Cases are reported, too, in Batavia,² among children in Kenya,³ where the disease is unknown in adults, and in the province of Venice, Italy,⁴ where pellagra disappeared almost completely after the great war but is now reappearing and increasing. In view of such widespread distribution a survey of some of the more prominent features of this disease may be of interest. The peak of incidence is between January and March in Lower Egypt⁵ and May and July in Georgia, U.S.A.⁶; in Kenya pellagra may be seen all the year round except in July and August. This geographical variation in seasonal incidence seems to depend on the time of harvesting cereal crops and on the seasonal variation of the intensity of sunshine. In Yugoslavia^{7,8} and in Georgia pellagra is much more common among women and in Egypt among men, probably because hard physical work in the open air is done by women in the former and by men in the latter pellagrous regions. Most Egyptian pellagrins are under 30, and the majority of American pellagrins are between 21 and 60 years of age. Skin lesions, glossitis and stomatitis, and diarrhoea affect equally sufferers in the different countries, but changes in the central nervous system, which were found rarely in Lower Egypt, more often in Upper Egypt, and

to no noticeable extent among the Kenya children, were very common in the American cases.⁹ Again in contrast to the findings in America, peripheral nerve lesions were absent in Egypt. The heart is reported to be unaffected in pellagra by some authors,¹⁰ while others¹¹ have often found the heart muscle degenerated. In Egypt infection with intestinal parasites is so usual that Ellinger, Hassan, and Taha thought pellagra "secondary" to this condition; such infection was also common in the pellagrous children of Kenya. Sydenstricker and Armstrong found other disorders in about 50 per cent. of their "endemic" pellagra cases, and three such cases examined post mortem by Spies and his co-workers¹² showed severe non-pellagrous lesions of the gastro-intestinal tract.

Theories of aetiology other than those concerned with defective nutrition have failed to survive for lack of evidence.¹³ The view that pellagra is caused by an amino-acid deficiency was put forward by Wilson¹⁴ in 1921, and seemed to explain the association of pellagra with the consumption of maize as a staple cereal, since about 60 per cent. of the protein of maize consists of zein, which lacks the essential amino-acids lysine and tryptophane. There is, however, a mass of experimental evidence showing that the total proteins of whole maize are not very inferior to those of whole wheat, and there are two observations in particular which indicate that pellagra cannot be due to a lack of good protein: the discovery of Voegtlin and his colleagues¹⁵ that a protein-free extract of liver was curative for pellagra, and the complementary observation of Goldberger and his co-workers¹⁶ that a large extra daily ration of purified casein did not prevent the disease. The idea that pellagra might be caused by a toxin, perhaps derived from moulds or other impurities in the maize eaten, has also been widely supported. Somewhat similar are the notions that the disease follows poisoning by dioxyphenylalanine (dopa) produced in the metabolism of maize and is amenable to treatment with sodium thiosulphate,^{17,18,19} or that it is due to chronic cyanide poisoning and curable by sulphur compounds.²⁰ Yet another view, based on similarities between selenium poisoning and canine black-tongue, is that pellagra is a form of selenium poisoning.²¹ None of these sug-

SATURDAY JANUARY 15 1938

BACTERIOLOGICAL DIAGNOSIS OF
TUBERCULOSIS

Examination of smears of suspected material by the Ziehl-Neelsen method has been of inestimable value in establishing a diagnosis of tuberculous disease in the lungs or other organs. But soon after the introduction of the method clinicians realized that in an appreciable proportion of patients it let them down because of the large numbers of tubercle bacilli required to be present in the material examined—estimated by Corper at over 100,000 per c.cm. of sputum, for instance—before bacilli could be detected in the smears. Concentration methods increased the percentage of positive findings. But as by culture an enormous multiplication of bacilli would occur, the possibilities of this method in clinical work were soon being explored. The attempts of Koch and others were unsuccessful because difficulties arose in excluding the growth of secondary organisms. Since 1900, however, the work of Spengler, Piatkowski, Uhlenhuth, Petroff, Petragani, Loewenstein, Höhn, and K. A. Jensen has led to the perfecting of a method of culture which is now being firmly established in the clinical field. Loewenstein showed that the tubercle bacillus was resistant to high concentrations of acid or alkali; moreover, he prepared a medium, containing egg, asparagine, and Congo-red or malachite-green, on which better and more easily visible growth of the bacillus occurred. Colonies of human bacilli generally appear within twelve to thirty days, bovine colonies not till after thirty days. The characteristics of the colonies of these two types are distinct enough to allow a diagnosis of type to be based on appearance alone, except in isolated cases when animal inoculation is required. Saenz and Costil¹ have recently claimed, moreover, that the date on which the result is obtained can be hastened by the examination of "microcultures." Seven or eight days after incubation a platinum loop is passed over the whole of the surface of one of the tubes inoculated (they recommend inoculation of several tubes), without injuring the medium, and any material collected is spread on

a slide and stained by Ziehl-Neelsen's method. The tube is then replaced in the incubator. If the result proves negative the same procedure is carried out on the other tubes on the eleventh, fifteenth, and eighteenth days until "microcolonies" are found, constituted by isolated, or masses of, bacilli. This procedure does not interfere with the ultimate growth of the colonies.

In this country Evelyn Holmes² first drew attention to the value of cultivation in the diagnosis of tuberculosis. Edwards, Lynn, and Cutbill³ have published some results; and the paper by Dr. C. A. Green, which appears elsewhere in this issue, indicates clearly what may be expected from the method in clinical practice. Among 2,788 specimens of sputum examined 19.7 per cent. were positive for tubercle bacilli by direct film, cultural, or combined examinations. Cultivation alone was successful in 98.3 per cent. of all positive results. As Dr. Green points out, the most significant finding was that only 74.3 per cent. of all positive results were detected by the routine film examination. Repeated examination by separate observers confirmed the absence of tubercle bacilli in the original stained smears of the 25.7 per cent. of sputa later proved positive by culture. The comparative results in pleural effusions, pus, urine, and cerebrospinal fluid were less striking, but still in favour of the method of culture. Correlation of the bacteriological with the clinical diagnosis left little doubt as to the reliability of the method. But it is evident that the practice of the method calls for expert technique and interpretation, and that animal inoculation may be needed occasionally for confirmation. For the errors that may be introduced into the method we would again refer the reader to Saenz and Costil.¹

Dr. Green stresses the point that cultivation much prolongs the time of examination for tubercle bacilli, and on this account careful choice should be made of the material submitted to the treatment. With this we entirely agree. That the direct film examination should be repeated two or three times (if possible) before material is cultured needs no emphasis. But addition labour may be wasted and a wrong significance attached to a negative result when unsuitable specimens are sent to the laboratory: for instance a specimen which is nothing more than saliva from a patient in whom only such material is obtained, a gastric lavage should be carried out, and the contents appropriately treated and cultured and inoculated in a guinea-pig. A method so obviously useful in diagnosis would not be without value in the treatment of tuberculous patients. The withholding of "quiescence" on the ground that

ALL THE WORLD A LABORATORY

An exhibition of scientific instruments, arranged by the Physical Society, attracted a large number of visitors to the Imperial College of Science, South Kensington, during the first week of January. It was divided into a trade and a research and educational section, but really the dividing line between the two sections was not very clear, because many trading firms are themselves carrying out important and far-reaching pieces of research. The relatively few instruments which had a medical interest were microscopes and other laboratory and class-room apparatus, hearing aids and acoustic measuring equipment—very much in evidence—long-wave diathermy apparatus, and an instrument called the “theracoupler” for raising the body temperature of patients by electro-magnetic induction. This instrument, which was exhibited by Marconi-Ekco Instruments Ltd., is intended for use either in general fever therapy or for localized disabilities. The oscillatory inductance takes the form of a flexible cable which may be wound around a limb or joint, looped over or under the body, or applied in the form of a pancake coil. The National Physical Laboratory showed a selection of the instruments used in its optical work, illustrating the routine tests it undertakes for a number of public bodies. One problem now being investigated is the effectiveness of the mercury and sodium discharge tubes which are increasingly used for street lighting. The question many people ask themselves is whether the colour is more effective than the white light for enabling the eye to detect objects on the roadway. Cinematograph records are being made of the manner in which uninstructed observers react to the different lights, the time they take to detect each of a number of objects being automatically recorded. The interest taken in noise control was shown by the number of sound-measuring instruments on view. One “noisemeter” was shown, a portable construction with a microphone, giving a direct reading in phons of the noise level in a vehicle or a factory or wherever it might be taken. The science of noise measurement appears to be established, but it is not entirely within the physicist's province to secure noise reduction. Another instrument that might perhaps be put to useful purpose was a volume indicator, to maintain at the appropriate level of audibility and comfort the loudness of reproduced speech and music in public places. An instrument shown for the first time was a gas-detection apparatus, the result of some work in which the Chemical Defence Research Department has been co-operating with the Department of Scientific and Industrial Research. It consists of a hand pump with a holder in which prepared test papers can be clamped. The suspected atmosphere is aspirated through the test paper and the stain produced is compared with standard colour charts. It was stated that concentrations of carbon monoxide of 0.2 per cent. can be detected in less than two minutes, and concentrations of 0.05 per cent. in six minutes. A new system of recording vibrations, accelerations, and the like was exhibited by the Cambridge Instrument Company in what they called

“stylus-on-celluloid.” The line produced by the stylus is so fine and smooth that when optically magnified readings accurate to about one-thousandth of a millimetre can be made. The recording is carried out in such a way that records taken over long periods occupy little space, are immediately available for inspection and measurement by using a simple form of microscope, and can be photographically enlarged.

PROPHYLAXIS OF MEASLES

Measles now ranks with diphtheria as a fully controllable disease, though the method of control is totally different and the only form of immunity which can be produced artificially is passive. What is perhaps more important than the fact that immune human serum will completely prevent an attack if given during the first five days after exposure to infection is the possibility, by reducing the dose or by giving it between the sixth and ninth days of the incubation period, of securing a mild attack which will confer permanent immunity. The day of the “measles tea-party” is returning, and deliberately to expose children to infection when a suitable opportunity occurs, and then by the appropriate use of serum to reduce the consequent attack to the level of German measles, would appear to be the ideal method of dealing with this disease. Deliberate exposure removes uncertainty as to the date of infection and enables the prophylactic dose and the time of its administration to be calculated with confidence in the result. The most potent serum is that obtained from convalescent donors within a few weeks of the attack, but the protective antibody persists throughout life and the serum of adults who have had the disease in childhood is effective. A quantity of blood such as is removed for transfusion may yield enough serum to secure a modified attack in from twenty to fifty children, according to their age and the time relations of its administration. An added advantage of this method is that human serum is free from all the drawbacks of therapeutic sera prepared in horses: it neither causes serum sickness nor sensitizes to further doses. It is in fact a most valuable therapeutic agent, and to render it more generally available will be an important service to the community. A recent report by Brincker and Gunn¹ gives details of the present sources of supply. The only product commercially available is obtained from placentas; and, according to this report, is liable to cause reactions; other sources are mainly local health authorities in London and a few other cities, which place restrictions on use of their stocks. The authors recommend that a serum pool be formed for use by members of the Medical Officers of Schools Association. There are doubtless many other attempts in progress to meet this demand on a smaller scale. It should be within the capacity of many laboratories to prepare serum for this purpose, and the organization of supplies for local use is a task which public health authorities might well undertake more generally. Where such facilities exist there is a corresponding obligation on the practitioner

¹ *Ann. Rep. Med. Off. Schools Ass.*, 1936, p. 92.

gestions has received adequate experimental or clinical confirmation.

The view accepted at present is that pellagra is a deficiency disease caused by lack of the vitamin B_2 complex. Two new variations on this theme are now under discussion. Sydenstricker and his co-workers²² state that pellagra can be cured simply by the administration of the gastric juice of healthy individuals. They conclude that pellagra is due partly to loss of the power to produce an intrinsic factor, secreted with the gastric juice and stored in the liver, and partly to the lack of an extrinsic factor, vitamin B_2 , in the diet. Stannus²³ considers the action of the anti-pellagrous factor in the diet to be that of a catalyst governing the metabolism of the cells of the skin, mucous membranes, and nervous system—an explanation somewhat difficult to follow. Quite different is the view advanced by Ellinger and others, after observing that rats deprived of the constituents of the vitamin B_2 complex excrete in the urine a highly concentrated coproporphyrin, which disappears after these substances have been added to the diet.²⁴ Clinical investigations along the same lines showed increased porphyrin in the urine in cases of "endemic" pellagra in Posusje, Yugoslavia, in "alcoholic" pellagrins in Cleveland, Ohio, and in Egyptian pellagrins. The porphyrin output appeared to be greatest before or at the onset of the disease and to decrease for a time while the clinical symptoms were developing; it usually disappeared after treatment with substances rich in vitamin B_2 . Porphyrin is thought to be an essential symptom of pellagra, and to cause the characteristic dermatitis by rendering the skin sensitive to light and pressure. The connexion between the dermatitis and exposure to sunlight has also been demonstrated by Smith and Ruffin.²⁵ The lack of vitamin B_2 causing pre-pellagrous porphyria may be due to malabsorption or malnutrition, or both; but once the pre-pellagrous state is established hard physical work, especially in the open air, exposure to sunlight, or the occurrence of infectious disease will precipitate the symptoms of pellagra. The clinical similarity of pellagra and congenital porphyria has also been stressed.

Treatment of pellagra has been advanced by the use of yeast, which reduced the death rate of pellagrins in Georgia from 33.7 per cent. before 1926 to 25.3 per cent. in the following nine years. Complete rest in bed, a diet containing as much as 4,500 calories, and the simultaneous administration of large daily doses of dried yeast or liver

extract has given striking results.²⁶ Ruffin and Smith,²⁷ investigating the pellagra-preventive dietary factor postulated by Goldberger and others,^{28,29} conclude that this factor in liver extracts consists of two or more substances. Ellinger, Hassan, and Taha³⁰ observed cure or improvement in pellagra following the oral administration of dried yeast or an autoclaved watery extract of yeast, without any other alteration of the diet or conditions of life. The fuller's earth adsorbate of the watery extract of yeast which Goldberger and Wheeler³¹ found effective in the prevention of black-tongue, believed to be the canine equivalent, gave no decisive results in human pellagra. An eluate prepared from the fuller's earth adsorbate gave promising results, as did the filtrate from this adsorbate when given with lactoflavine. These substances were prepared according to the methods of Edgar and Macrae,³² who tested them on growing rats deprived of vitamin B_2 , and found them to possess growth-promoting activity. The activity of the fraction isolated has been tested in most instances on rats or dogs, and the application of the results to human pellagra is difficult and uncertain in the present state of knowledge. Much confusion exists owing to the different sources (yeast, liver, rice bran, etc.) from which various fractions have been isolated and to the lack of a uniform nomenclature for them.

A further complication has been introduced by Leutsky,³³ who suggests that there is reason to seek the cause of pellagra-like lesions in mice in an insufficiency of mineral components in an otherwise adequate diet. In the treatment of canine black-tongue Elvehjem and his co-workers³⁴ found nicotinic acid of value and isolated nicotinamide from highly active liver concentrates. If these results are confirmed and nicotinic acid is found equally effective in the treatment of human pellagra as seems to be the case from the results recently published by Fouts and others³⁵ and by Smith, Ruffin, and Smith,³⁶ it will be interesting to see whether the consumption of trigonellin, the methyl betaine of nicotinic acid, has any influence on the development of pellagra in Lower Egypt. Trigonellin is contained in "helba," the seed of *Foeniculum foenum graecum*, which is a common constituent of the bread eaten by the rural population of this district, where pellagra is endemic.

was increased, so that much serous exudate escaped into the tissues. Blackman considers that the formation of this exudate is characteristic of lead encephalitis, as the picture which results from its formation has not been observed in any other type of encephalitis. The exudate causes distortion of the architecture of the brain, the regions in which exudate collects showing destruction of nerve cells and fibres, with overgrowth of neuroglial fibres around the cells that have been destroyed. During fixation of the brain some of the exudate escapes into the fixing fluid, leaving large spongy areas in the brain, especially in the grey matter and in the apical white matter. Similar lesions are found in the cerebellum, particularly in the molecular layer, the Purkinje layer, and in the dentate nucleus. Small perivascular haemorrhages and focal areas of necrosis are common but are not specific. Special stains are recommended for demonstration of the exudate. A point of particular interest was that most of the children developed encephalitis and died during the summer—nineteen out of the twenty-two cases succumbed during the hottest time of the year. The suggestion is made that the high seasonal temperatures, which cause vasodilatation, may possibly precipitate the onset of encephalitis by acting on vessels already weakened by the toxic effects of lead.

THE JOURNAL OF NEUROLOGY AND PSYCHIATRY

The first issue of the *Journal of Neurology and Psychiatry*, dated January, 1938, has been published this week by the British Medical Association. As it is the lineal descendant of the *Journal of Neurology and Psychopathology* the aim of the editors is to uphold the traditions, character, and standard handed down by the late Dr. Kinnier Wilson. The present number contains original papers dealing with various aspects of neurology and psychiatry and a critical review of the pathology of apoplexy. It has been decided to replace the editorial article of the previous journal by an authoritative critical survey of some particular subject. The choice of subject under review will be guided largely by the type of work being carried out at various hospitals and centres of research. In this way it is the desire of the editorial committee to keep readers abreast of the latest additions to knowledge in neurology and psychiatry. To aid in the same purpose, each issue will also include an epitome of current literature in which the contents tables of recently published numbers of journals devoted to these branches of medicine are reproduced, along with short abstracts of articles of special interest. Appreciating the need for keeping in touch with the basic sciences, the scope of the epitome will embrace journals of anatomy, physiology, and biochemistry. The critical reviews and the epitome should be of much value to neurologists and psychiatrists throughout this country, the Dominions, and the United States, because there is at present no adequate service in the English language for bringing to their notice in compact form work which is going on in the world. To assist Dr. E. Arnold Carmichael

in editing the *Journal of Neurology and Psychiatry* a board has been set up consisting of Dr. D. E. Denny-Brown, Mr. Geoffrey Jefferson, Dr. Aubrey Lewis, Dr. R. A. McCance, and Dr. Alfred Meyer. The medical public is thus assured of a quarterly periodical of high standard which, with its new typography and lay-out, deserves the support of neurologists and psychiatrists in all parts of the British Empire. It is not too sanguine to expect that, with the standard set by the editorial board in this first number, our contemporary, under a new name and a wider policy, will become recognized everywhere as being authoritative and invaluable to those engaged in the study and practice of the subjects covered by its title.

WORKMEN'S COMPENSATION FOR SILICOSIS

The group of pulmonary diseases known as silicosis attack a large number of workmen in countries where much mining is done in siliceous rock. The problem of silicosis was one of the first to be dealt with by the International Labour Office at Geneva, which has published a considerable body of literature on its researches. The International Stoneworkers' Secretariat has for long pressed the Office to help it to obtain compensation in all countries for silicosis, and in the course of its investigations the Office has examined the compensation legislation in force in various countries. This legislation mostly falls within three typical systems: special legislation, special schemes within workmen's compensation legislation, and schedule. These are represented by practice in Great Britain, South Africa, and Germany respectively. In a recent report on workmen's compensation for silicosis in the Union of South Africa, Great Britain, and Germany¹ the Office has analysed these systems of law according to a uniform plan, and compared the results. In a series of appendices it gives an account of the system of blanket coverage and its practical application, data connected with radiological technique and terminology, enumeration of products used and of industries, statistics of incidence and cost of compensation, and a list of countries which have introduced compensation.

THE HALF-YEARLY INDEXES

The usual half-yearly indexes to the *Journal* and to the *Supplement and Epitome* have been prepared and will be ready shortly; they will, however, not be issued with all copies of the *Journal* but only to those readers who ask for them. Any member or subscriber who wishes to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Secretary, B.M.A. House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this.

¹ International Labour Office. Studies and Reports. Series F (Industrial Hygiene), No. 16. Workmen's Compensation for Silicosis in the Union of South Africa, Great Britain, and Germany. Geneva, 1937. Price 3s. 6d. Published in the United Kingdom by P. S. King and Son, Ltd., Orchard House, 14, Great Smith Street, Westminster, S.W.1.

to use the serum to the best advantage. Every case in which the date or the fact itself of exposure to infection is in doubt has to be judged on its own merits, but two indications are quite clear: that serum is wasted if given after the attack has begun, and that absolute prevention of an attack should be sought for only in infants or in children who, by reason of other illness are unfit to undergo even a modified attack.

SCHOLARSHIPS AND GRANTS FOR RESEARCH

The *Supplement* this week (p. 34) contains an announcement of the five scholarships which the British Medical Association awards annually and for which it is prepared now to receive applications. The value of the scholarships, which are tenable for a year, is £200 each in the case of the Ernest Hart Memorial Scholarship and the Walter Dixon Scholarship, and £150 for each of the other three. Grants to assist research are also made annually, and both scholarships and grants are awarded by the Council of the Association on the recommendation of its Science Committee. Applications for scholarships and grants should be made on forms prescribed for the purpose, which are available on request, and should reach the Secretary of the Association not later than May 7, 1938.

EFFECTS OF TEMPORARY CORONARY OCCLUSION

Following upon the recognition of certain changes in the electrocardiogram after myocardial infarction, many examples of changes similar in type, if less in degree, were reported in angina of effort. The changes in the latter, like the pain, lasted only a few minutes, but it is believed that functional changes, due to a temporary ischaemia, occur in the muscle during this time, and that with the return of a normal balance between work and blood flow the pain and the metabolic changes disappear. It is known that myocardial infarction may arise with widespread narrowing of the coronary branches but without complete occlusion of any vessel; but it is not certain whether the periodic increases of chronic ischaemia, expressed as attacks of effort angina, are a factor in the production of infarction in these cases. Some animal experiments to determine the electrocardiographic and other effects of temporary coronary occlusion have been made by H. L. Blumgart *et al.*,¹ the anterior descending branch of the left coronary being occluded in cats for periods of five to forty minutes. In all the animals where the occlusion was from fifteen to forty minutes the tracings showed the changes of infarction, and these persisted till the animals were killed—that is, for periods up to nine days. With occlusion for less than fifteen minutes these changes did not always occur, and when they did persisted a shorter time. In no case was any gross or microscopical evidence of infarction discovered in the hearts, and it was shown that the circulation through

the occluded vessel was fully re-established after removal of the ligature. During the experiments ventricular fibrillation was often noted; the onset of the arrhythmia was most frequent at the release of the ligature and, secondly, just after its application. The mechanical trauma which would take place at these times may possibly explain this. There are doubtless clinical counterparts to these results. Cases have been recorded in which an apparently sound clinical diagnosis of myocardial infarction confirmed by electrocardiogram has not been borne out by post-mortem examination. Anginal pains of a duration comparable to that of Blumgart's experiments occur in the varieties known as angina decubitus and spasmodic angina, and are held to be independent of infarction. Also, progressive changes in the T waves are often seen in patients who give a history of nothing more than angina of effort. In all of these groups it is possible that chronic progressive changes in the electrocardiogram may appear and in some be indistinguishable from those of myocardial infarction. Increasing knowledge of these conditions will probably show that the present-day tendency is to diagnose cardiac infarction too readily.

LEAD ENCEPHALITIS IN CHILDREN

Lead poisoning is usually considered to be an industrial problem, and the development of public health services, with their influence on industrial medicine, has resulted in a great decline in the number of workers who contract this occupational disease. Of the protean manifestations of lead poisoning none is more serious or irrecoverable than encephalitis, which is often fatal. This encephalitis may arise either in acute lead poisoning or in chronic cases. The nature and pathology of lead encephalitis in adults have long been recognized, but little has been known about its occurrence in children until recently, when an outbreak of lead poisoning in small children caused by chewing furniture and toys coated with lead paint stimulated interest in this subject in the United States. Whether such cases occur in this country and escape recognition, or whether British children have less depraved appetites than their American cousins, cannot be determined at present. All that can be said is that in Great Britain lead encephalitis is a very rare diagnosis in children. The fact that Blackman² was able to study the pathology of the brain in twenty-two fatal cases of lead poisoning in children between the ages of 13 months and 7 years. Most of these cases were in coloured infants, but there were in white children. Evidence of lead poisoning was available in every case, both from the history and from the clinical picture. On naked-eye examination the brains appeared highly oedematous and congested. Microscopically, lesions were found throughout the nervous system, but were most abundant in the cerebral hemispheres and in the cerebellum. Most of the damage to nervous tissues resulted from changes in the small cerebral vessels, the permeability of

¹ *Amer. J. med. Sci.*, 1937, 194, 493.

² *Johns Hopk. Hosp. Bull.*, 1927, 21, 1.

Haemorrhage can usually be arrested by local pressure—the application of a first-aid dressing with a firm bandage over it. Under the conditions implied by first-aid, when the dressings are from a stock packet sterilized some time previously and there are no facilities for boiling instruments or adequate preparation of hands, opening the wound or packing its depths should be avoided. Should this seem essential for life-saving, the packing gauze, if possible, should be wrung out of an antiseptic. For severe haemorrhage from a limb a tourniquet provides a certain method of arrest, one far safer than packing under doubtful conditions. A tourniquet should not be left on the arm longer than half an hour if it can be avoided, and in no case longer than an hour; in the leg these times may be doubled. In the arm the dangers of a tourniquet are not alone those of tissue necrosis following prolonged ischaemia; paralysis of some of the nerves, usually temporary but occasionally persisting as a partial weakness, is to be feared even after a short application of any band of a rigid type. Here it is safer to use the cuff of a sphygmomanometer.

Tincture of iodine is universally painted over wounds as a first-aid measure. That this practice should be retained in ambulance classes is probably wise; the use of iodine discourages meddlesome exploration, re-sterilizes dressings which have often been de-sterilized in application, and brings a visible and pungent reminder of the value of antiseptics. When a really sterile dressing can be applied with careful technique iodine is better omitted. In a fresh wound it is extremely painful, and to one whose nerves have been upset by a recent accident very distressing, while its sterilizing action is limited to the skin and the dressings and does not extend appreciably to the depths of the wound, the proteins of which are coagulated by the alcohol. When haemorrhage has been arrested and a clean dressing applied the part should be fixed on a splint or otherwise protected from avoidable movement.

General Treatment

As soon as the patient reaches a place where adequate treatment can be instituted—his house or the doctor's, a nursing home or hospital—a more careful study of him and his injury must be made. We must ascertain as far as possible the extent of the wound, the degree of contamination, and the structures that have been injured. This examination may mean gently lifting up the flaps of the wound with forceps and cautious probing, but any forcible separation of the parts, anything that may hurt the patient or restart the haemorrhage, should be postponed till an anaesthetic has been given. At this stage a careful search will be made for nerve and tendon injuries and for fracture of neighbouring bones. Such a survey will allow us to decide whether the general condition of the patient demands treatment for shock or whether we may proceed to repair the wound at once; whether an anaesthetic is necessary, and if so of what nature; what structures are certainly damaged and need repair; and if infection is to be feared, particularly infection by some of the more dangerous organisms.

It is rarely that treatment for shock is essential before the wound can be repaired, and then only if it appears reasonably certain that active haemorrhage plays no part in the shock. Because of the difference outlined above between contamination and infection it is really important that the surgical toilet of the wound shall be delayed as little as possible and that bacteria should not be allowed to establish a hold. The treatment of shock by warmth

and the administration of fluids can in most cases be carried on while the wound is being repaired. If necessary a local anaesthetic can be given.

Preventive Therapy

While infection may be present and is to be feared in any wound, there are three organisms whose presence can often be anticipated and whose ravages can be forestalled—the bacillus of tetanus, the bacillus of gas gangrene, and the haemolytic streptococcus. The bacilli of tetanus and gas gangrene are both found in the alimentary flora of farmyard animals, and therefore in stables and on all manured land, on the surface of roads, and in the clothing of those who work in gardens or with horses or cattle. Either bacillus may gain entry to wounds incurred in such surroundings or by people in these occupations: but whereas the tetanus bacillus will establish itself wherever anaerobic conditions are found, the *Cl. welchii* rarely gains a foothold except in the presence of grossly devitalized tissues. A prophylactic dose of 1,000 English units of antitetanic serum (2 English units correspond to 1 U.S.A. unit) should be given in all cases of road or farm accidents, and indeed in every case of a lacerated wound where soiling is at all possible: a prophylactic dose of 4,000 units of anti-gas-gangrene serum should be given in addition where soiling and laceration coexist.*

Infections with virulent strains of haemolytic streptococci are rarely encountered, except in wounds inflicted in hospital practice. In pricks or scratches incurred during necropsies, or while operating on or dressing septic cases, they may almost be anticipated, and are notoriously dangerous and even fatal. In such cases a prophylactic dose of sulphanilamide should be given.

Anaesthesia

The question of anaesthesia demands little discussion. Trivial wounds, and occasionally larger ones in phlegmatic adults, may be stitched without anaesthesia. If the patient has not to make a journey afterwards a preliminary injection of morphine may be given to allay apprehension. In most cases a general anaesthetic will be found advisable, since it leaves the surgeon free to extend his procedures in time or space, and it is almost essential if a tourniquet is to be applied or haemorrhage is anticipated. Local anaesthesia is particularly applicable to wounds below the knee and elbow. The method of local infiltration is not really suitable for the repair of wounds, and some form of nerve block will be preferred. Fortunately the median, ulnar, and radial nerves at the elbow and wrist, and the internal and external popliteal and long saphenous nerves at the knee, run in easily identified anatomical sites, and may be blocked by injection with 1 per cent. novocain. Local anaesthesia is indicated when the wound is part of an injury that includes fractures of the ribs, since pulmonary complications may follow general anaesthesia, however carefully administered.

Operative Treatment

The aim of the surgeon is to suture healthy, uninfected tissues as accurately as possible. When the wound has been inflicted with a clean sharp instrument, the tissues on its surfaces are undamaged, and the edges of skin and deep layers clean-cut, the wound may be sewn up completely after gentle irrigation with a harmless antiseptic,

* Many surgeons now give a mixed tetanus and gas-gangrene antitoxin in all road and industrial accidents: this is prophylactic against infection by *Cl. tetani*, *Cl. welchii*, and *Vibrio septique*.

SURGICAL PROCEDURES IN GENERAL PRACTICE

This is one of a series of articles contributed by invitation

TREATMENT OF WOUNDS—I

BY

W. H. OGILVIE, F.R.C.S.

The aim of wound treatment is the restoration of perfect function: to attain this end the wound must be made to heal in the shortest time, with the least alteration in its structures by the processes of repair.

The Process of Repair

The ideal progress of a wound is, or should be, seen in the healing of a surgical incision. An operation wound differs in several particulars from the majority of accidental wounds: first, it is executed with sharp instruments, used in their cutting plane only, and the damage to tissues along its margin is therefore slight; secondly, there is no loss of substance; thirdly, haemorrhage has not been allowed to take place; and, fourthly, infection is absent or minimal. After suture the first change that takes place in such a wound is the outpouring of fluid between the apposed cut surfaces. Into this fluid and between these surfaces phagocytes wander, and proceed to engulf and remove damaged cells—in the case of a clean wound to a depth of a few cells only. The fixed connective-tissue cells of the part multiply and bridge the gap, and on the surface the epithelial cells do the same. After four days the epithelial wound if linear is covered with fresh cells, and the deeper parts are bridged by new connective tissue. After ten days the wound is mechanically very nearly as strong as the normal parts on each side of it, but the newly united tissues are more cellular and vascular. By the end of six weeks mature connective tissue has replaced the fibroblasts and repair may be looked upon as complete.

In traumatic surgery an imperfect result may be due to the nature of the wound alone, the process of healing having proceeded normally, or to permanent interference with the function of the structures in the neighbourhood of the wound due to delayed or imperfect healing. In the first case there has been actual loss of substance which cannot be replaced, and the resulting disability will depend upon the extent and importance of the tissue lost. We can do nothing to mitigate or to prevent this loss. In the second case repair has been by second intention—that is, it has passed through an intermediate stage of granulation. Granulation tissue is not in itself vicious. It is Nature's method of dealing with a dead space, the putty she puts into imperfections before finishing off. Granulation tissue must therefore be expected where the loss of substance has been too great for the tissues to be approximated by suture; where approximation, though possible, has been imperfectly performed; or where it has been broken down later by haemorrhage or infection. The evil of granulation tissue is that it is finally replaced by a fibrous tissue which contracts to approximate the margins of the defect it originally filled. Its purpose is to bind, fix, and repair; its vice that this fixity destroys movement. The skin over a granulated scar is thin, fixed, prone to break down with friction, and liable to keloid or even malignant changes later; muscles are weakened in proportion to the gap in their fibres, and bound to each other by adhesions; tendons become fixed

to their neighbours and their sheaths; nerves regenerate poorly if at all.

If our ideal is to be the approximation of healthy tissue without infection we must, in each case that presents itself, assess both the mechanical and bacteriological condition of the wound. From one point of view wounds may be classified as punctured, incised, lacerated, crushed or complicated by injury to bones, joints, or nerves. From the other they fall into the categories of clean and infected. The two are not really independent, for wound infection depends not alone upon the entry of bacteria but on the presence of dead or damaged tissues upon which they can thrive and establish a foothold. In general, clean-cut wounds are more likely to be bacteriologically clean than lacerated ones, but this is by no means always the case; among the most dangerous are the small punctures caused in hospital work by infected needles.

Contamination and Infection

The progress of a wound infection may be divided into two somewhat arbitrary stages—contamination and infection. In the first stage the bacteria which have been carried in by the agent inflicting the wound lie on the surface—in bits of dirt, clothing, or metal fragments—or in small groups in the blood clot. They are a local contamination and have not yet started to multiply or invade. They can, at this stage, be removed by a thorough mechanical cleansing, leaving the tissues round them uninfected. In the second stage the bacteria, profiting by the supply of culture medium available in them in the dead matter around, in blood clot, lymph, and damaged muscle, have multiplied and started to invade the tissues of the host. They can now be removed only by the protective reaction of the living cells, or by some wide excision which necessitates the removal of healthy tissues, and involves the risk that it may breach the defence wall without including in its scope all the invaders. For practical purposes the stage of contamination may be looked upon as lasting for twelve hours before it passes into that of infection. It must be remembered that where the organisms introduced are few the available pabulum scanty, and the tissues are healthy, infection may never establish a foothold.

An estimation of the probable degree of infection is the first step in deciding upon the treatment of any wound. This will take into consideration the nature of the injury, the state of the patient's skin and clothes, and the appearance of the wound, and will be no more than a working guess based upon experience, but a guess upon which treatment must be decided. If the wound is clean it should be sewn up completely; if infected, it should be drained. When there is any doubt undue conservatism is safer than mistaken optimism.

First-Aid Measures

These should be of the simplest character and limited to absolute essentials—the arrest of haemorrhage, the protection of the part from infection and further damage. They are only necessary when some competent person is not at hand and when the interval in time or space before proper treatment can be undertaken is appreciable.

CROYDON TYPHOID INQUIRY

CLOSING PROCEEDINGS

The Croydon Typhoid Inquiry reached its final stage at the beginning of the present week. It had extended over sixteen days. The evidence on behalf of Croydon Corporation was completed by the calling of the town clerk, Mr. Ernest Taberner, who, in reply to Mr. A. H. Forbes, for the Croydon Division of the British Medical Association and the Local Medical and Panel Committee, said that his council favoured co-operation with local medical practitioners, though it had not exercised the powers of co-optation afforded by the Local Government Act, 1933. He had no doubt that as the result of the present proceedings it would take the suggestion into consideration. He thought that it would not have been feasible at the beginning of a serious outbreak for the medical officer to take himself away from his work and set up a body of medical practitioners for the purpose of co-operation.

Dr. O. M. Holden, the medical officer, who was recalled, said in reply to Sir Humphry Rolleston that he began to be concerned about the cases on October 30, when four cases had been notified and two others were suspected. The infection of the Addington well by a typhoid carrier was in his view the most probable cause of the outbreak, though he agreed with the chairman that this did not imply any wilful misconduct on the part of the carrier or any other person.

Evidence by Residents

A number of witnesses were presented by Mr. A. M. Lyons on behalf of the South Croydon Typhoid Outbreak Committee. Among these was Mr. R. L. Moss, secretary of the committee, who said that at a meeting of residents on October 31 Dr. Holden had stated that water as a source of infection was "inconceivable." Another witness was a local councillor, Mr. S. A. Maycock, who said that he as a councillor received no information of the outbreak until November 9, when an official statement was made to the council at the mayor-making ceremony. Mr. Maycock added that his son had been a typhoid patient, but was now recovering. Asked whether he was in hospital, Mr. Maycock replied, "No, emphatically not; we kept him at home." Other witnesses included a hotel proprietor, a local schoolmaster, the matron of a nursing home, and Mr. C. R. Rimington, whose son was taken ill as early as October 24 and died of typhoid. On October 29, having heard of other cases in the road in which he lived, Mr. Rimington wrote to the medical officer of health mentioning these cases and stating that the only common thing appeared to be water. On October 30 he saw Dr. Holden and offered to place himself entirely at the medical officer's disposal in investigating the outbreak. He called an emergency meeting of local ratepayers on the following day, and it was at this meeting that Dr. Holden said, in reply to a question, that it was inconceivable that water was the cause.

The last of this series of witnesses was a typhoid patient, Mr. Cecil E. Green, who stated that he was taken ill on November 20 and removed to Mayday Hospital, which he had been allowed to leave for the first time on the day on which he gave evidence. He desired to take the opportunity of expressing his high appreciation of the medical, nursing, and domestic attention he had received at the hospital, against which, he understood, some adverse criticism had been directed. Mr. Lyons said that no such criticism had been made by those he represented, and he wished to dissociate himself from anything of the kind. Mr. Green confirmed the testimony of previous witnesses that at the meeting of residents on October 31 the medical officer was asked if he thought that water was the cause of the trouble, and replied that this was inconceivable, because the water was tested. He was asked at the same meeting whether it would not be a good idea to inform local practitioners of the outbreak, but Dr. Holden did not

agree that at that time there was an outbreak, and that was one of the reasons why the residents were dissatisfied with the results of the meeting.

Sir William Willcox's Evidence

Sir William Willcox was also called by Mr. Lyons. He said that he desired to make certain statements in the interests of the public. The Croydon outbreak in his view was an epidemic of a rather serious form of typhoid, with clinical manifestations a little unusual. The mortality rate looked like being 15 per cent., which was fairly high. In reply to questions, he said that if there were five or six cases of typhoid in the same area, as was the case in Croydon by October 31, his suspicions would have been aroused, and his attention would first have been drawn to water and milk. In dealing with such an outbreak he would advise close liaison between the medical officer of health, the municipal authority, local medical practitioners, and the voluntary hospitals.

"I am not criticizing the medical officer of health for Croydon, but I do criticize the machinery which exists throughout the country to-day, and the lack of liaison between the general health and municipal authorities and general practitioners. There should be some *ad hoc* committee representing the medical practitioners of the district who can advise the medical officer if called upon and who can in turn be helped by the medical officer."

He quite agreed that it was the responsibility of the medical officer of health to deal with an outbreak, and that it would not be possible in the midst of such an outbreak for the medical officer himself to go round to all the local doctors. He added that he was of opinion that the cause of this epidemic was discovered very quickly. "It was a good piece of work. From a scientific point of view the diagnosis in this case was very quickly made." He was sure that Dr. Holden did everything possible to help the doctors. The outbreak was rather sprung upon him, and perhaps he did not realize the importance of the help that a committee might have afforded.

At the conclusion of Sir William Willcox's evidence Mr. Sandlands (for Dr. Holden) said that although he had previously stated that he would call a witness, he would not now do so in view of Sir William's commendatory observations regarding the medical officer.

Other Medical Evidence

Dr. George Lewin, who said that he had attended twenty-three cases during the present outbreak, urged that it was not enough merely to circularize the practitioners of South Croydon. All the practitioners in the borough and the surrounding districts should have been warned earlier, and a map of the water supply in relation to the occurrence of cases would have been of great assistance. Replying to the chairman of the tribunal (Mr. H. L. Murphy, K.C.) he said that had he been medical officer when the outbreak occurred he would have suspected water from the very beginning and have informed the practitioners—in confidence, if necessary—of the fact. The general practitioners bore the frontal attack in an outbreak of this kind, and the M.O.H. was the intelligence officer.

Dr. E. T. Conybeare, a medical officer of the Ministry of Health, who had assisted in Croydon from the beginning of the outbreak, answered some questions by the chairman. He thought that the coincidence between the dates on which the known carrier was working in the well and the probable date of infection in the majority of the cases pointed to the probability that this man was connected with the outbreak, though not the cause of it in the gross manner which had been indicated. He was of opinion that the incubation period in typhoid was longer than fourteen days. Dr. Macdonald Scott, bacteriologist at the Ministry of Health, gave evidence that his examination showed that one of the workmen was a

such as 1 in 1,000 acriflavine, and the arrest of all bleeding and oozing points. Such an apparently clean wound almost necessarily contains organisms; but these, if small in number and of low virulence, will be exterminated by the healthy tissues around them if no circumstances favourable to them, such as the accumulation of exudate or the presence of foreign material, are allowed to appear. Dead spaces must be eliminated, so the wound must be sutured to its depth; it is not sufficient to approximate the skin. For the deep sutures catgut of small calibre should be used, but used sparingly. Size 00 is usually sufficient, and the sizes larger than 1 are seldom needed, being bulky and irritating to the tissues rather than strong. For the skin unabsorbable sutures of horse-hair or fine silkworm gut are best. An ideal material is the suture of 00 ophthalmic silkworm gut, which is supplied by most firms in sterile tubes for plastic work, on fine eyeless cutting needles. These sutures can be inserted almost painlessly without anaesthesia and leave no visible scar when removed. All stitches in deep structures or skin must be interrupted to allow any fluid accumulating to escape between them, and beyond this precaution drainage is unnecessary in the clean type of case under discussion. If, on the other hand, the wound is lacerated and soiled it must be trimmed and cleansed before it can be sutured, and even then it should not be closed completely unless the excision has been wide and early; usually drainage of some kind must be allowed.

Such a wound is first opened freely and its depths inspected. Loose blood clot, dirt, and fragments of clothing are removed, and the cavity is lightly sponged out with gauze swabs. If bleeding from a vessel of some size is then encountered it must be stopped; otherwise the arrest of haemorrhage should be left till obviously damaged tissues have been excised. Excision is carried out methodically and carefully from the deeper to the more superficial layers. The torn surface of muscle should be trimmed with scissors to the depth of a few millimetres. Vessels and nerve trunks must of course be left, and can only be cleansed in so far as swabbing with an antiseptic will do it. In most lacerated wounds the subcutaneous layer appears to be most soiled and must be methodically trimmed, care being taken, however, to remove only as much as is badly damaged, and not to interfere with the blood supply of the skin flaps. Skin should be removed very sparingly, the bruised edge alone of the flaps being cut away with a sharp knife.

Haemorrhage should be arrested, where possible, by ligature of the bleeding point. After the excision of bruised tissue the point of emergence of the jet of blood from the clean surface should be seen comparatively easily, and the point can be picked up with artery forceps and ligatured. If excision has been done under a tourniquet the vessels appear as the band is loosened. Blind diving for bleeding points that cannot clearly be seen is to be deprecated, for arteries and nerves usually run together, and the nerve may be seized with, or instead of, the vessel. Ligature of large masses of tissue should also be avoided, as being liable to lead later to sepsis. While the actual bleeding point should be picked up and tied, under the conditions of poor light, inadequate assistance, and inefficient anaesthesia in which wounds often have to be treated such a course may be unwise. Bleeding may continue, and its source appear to lie deep in an interosseous space or near some important structure, where the operator is unwilling to adventure under the circumstances prevailing. Here packing offers an alternative method of arrest, and one that is immediately effective,

though ultimately far less certain than ligature. In the type of case being discussed a packed wound inadequately excised is almost certain to become infected to some degree, and secondary haemorrhage, demanding ligature of the main artery to the part at a distance, is very likely to follow at any time in the ensuing ten days. When a wound has been packed to arrest bleeding the pack should be removed two or three days later, a second pack being ready for immediate insertion should the bleeding restart.

Drainage and Delayed Primary Suture

A wound lacerated and soiled enough to require excision can rarely be sutured up completely. In most cases a small drain, preferably a length of corrugated rubber or a strip cut from a surgical glove, should be put down to its depth and brought out between two stitches. The drain can be removed as soon as lessened discharge and normality of temperature and pulse show that there is no infection in the depth of the wound; if it comes out within forty-eight hours the cosmetic result will be that of an undrained wound without its risks. In small wounds a very satisfactory temporary drain can be made by a wisp of six to ten strands of silkworm gut laid side by side, some or all of which can be removed as the wound clears up.

If the excision has been incomplete or if the wound has been grossly contaminated, and in all cases of large and dirty lacerations repaired later than twelve hours after infliction, it is better to pack the wound at first, or at most to close it in part only. The method of "delayed primary suture," used with success in the war, is particularly applicable to these dangerous cases. The wound is excised, and after haemorrhage has been arrested it is carefully packed with strips of gauze soaked in 1 in 1,000 acriflavine, care being taken that all recesses are filled and that no pockets remain in which serum can accumulate. The abortion of infection is judged by the general condition of the patient, the state of his temperature and pulse, the absence of pain, and the normal appearance of the parts around the dressing. If these indications are satisfactory the packing is removed after two or three days under general anaesthesia, and if the wound appears healthy its sides are brought together over a small drain with catgut mattress sutures for the deeper parts and interrupted silkworm-gut stitches for the skin.

After suture the wound is dressed with sterile gauze and wool and bandaged firmly enough to keep the deep layers apposed and discourage oozing. The injured part must be kept immobilized for at any rate the first week after suture. This may imply rest in bed, confinement to the house, a sling, or, in many cases, a splint. Rest is essential to prevent effusion, aid repair, and assist the tissues to overcome infection. It is far better overdone than omitted. For these reasons a splint is often advisable to immobilize the whole of an involved limb segment and, in some cases, to maintain a position which relaxes the sutured planes.

(To be continued)

The Medical Society of Evian is organizing a second congress on renal insufficiency, which will take place at Evian from September 21 to 24, under the presidency of Professor F. Rathery. Titles of papers to be read at the congress should be sent to the secretaries, Dr. F. P. Merle and Dr. M. Derot, before July 15. All communications or inquiries should be addressed to the Secrétariat du Congrès, 138, Avenue des Champs-Élysées, Paris, Rome.

to do and of which no mention was made. Every doctor who wanted help could obtain it from the office of the medical officer. At the invitation of the doctors of Croydon Dr. Holden or his deputy had paid no fewer than fifty visits to patients in their homes. He mentioned that as showing that cordial co-operation did exist between the individual medical men who wanted help and the medical officer whose duty it was to supply it. In addition there were multitudinous arrangements to be made—samples to be taken, laundry supervision to be instituted, a great increase of hospital accommodation and nursing staff to be provided. All these were matters which should be considered in judging the work and the responsibility of the medical officer during the strenuous and anxious period.

The closing speeches of the Inquiry were made by Mr. Lyons, K.C., on behalf of the South Croydon Typhoid Committee, and Sir Walter Monckton, K.C., on behalf of Croydon Corporation.

On the last day of the hearing (January 11) it was announced that the total cases numbered 290, no fresh cases having been notified for several days. The number of deaths was 38. A bulletin outside the town hall stated that six patients were still dangerously ill with typhoid at Mayday Hospital, and seven others seriously ill.

EDUCATION AND HEALTH

CONFERENCES OF TEACHERS' ORGANIZATIONS

Over fifty educational associations combined for a five-day conference during the first week of the New Year at University College, London. As many as six meetings were sometimes taking place simultaneously, and the crowded theatres and corridors bore witness to the enthusiasm of the teaching profession. Several of the sessions were occupied, directly or indirectly, with the subject of health in the schools, and the Government's physical fitness campaign was often referred to, and at times critically examined.

The Minister of Health (Sir KINGSLEY WOOD) was president of the conference, and in an inaugural address on the subject of "Education and Health" ranged over the activities of his department. He mentioned that the new midwifery service would be seen in almost full operation throughout the country during the present year. Already some 7,000 midwives had been appointed. Lord DAWSON OF PENN, who proposed a vote of thanks to the Minister, said that an improvement in the maternal mortality figures might be hoped for in the near future, but it could not be repeated too often that in the earnest advocacy of the importance of reducing maternal mortality care must be taken not to frighten those young people who had maternity in front of them. Lord Dawson said that members of the medical profession were thinking more than ever in terms of education, and it was important that all those posts which were concerned both with education and health should be open to all medical men and women.

Health in the Schools

Sir FARQUHAR BUZZARD presided over a joint conference of all the organizations on the subject of "Health in the Schools." He stressed the importance of games, recreation, rest, diet, and fresh air, as well as the mere physical exercises, in the national campaign which had for its object a higher standard of physical fitness. The conference was addressed by Mr. M. L. JACKS, head master of Mill Hill and director-elect of the Department of Education, Oxford University. He dealt with certain forms of "sickness" which were specially the concern of the teacher, such as lack of power to develop skill, lack of knowledge of muscular potentiality and economy, and

inability to sit, stand, or move with grace and ease. The first necessity was to create in every public school a department of physical education, on a level with other departments such as modern languages, and with a university graduate to direct it. The interest of the director should be in the individual, particularly the weakling, rather than in the class. Mr. Jacks said that in his own experience he had discovered that whereas at about the age of 16 a boy normally put on about two pounds in weight every term, in the term in which he took the school certificate, generally at the age of 16½, there was a tendency to stand still or to lose weight. This indicated one of the strains and stresses which the director of physical education would have to bear in mind.

Criticism of the physical fitness campaign came from the high mistress of a girls' school, Miss ETHEL STRUDWICK of St. Paul's, Hammersmith. The word "fitness" was too closely associated with advertisement. She had never found it easy to believe that medicines or anything else which were widely advertised on the hoardings really did anybody any good. She distrusted the advertisement part of the campaign because she feared it might mean an artificial boom followed inevitably by a slump. Nor did she like the idea of middle-aged women being encouraged to emulate the poster-girl and poise on one toe!

Medical Aspects of Backwardness

In his address to the Medical Officers of Schools Association Dr. R. G. Gordon said that backward children might be divided into three classes—those who were born stupid, those who acquired stupidity, and those who had stupidity thrust upon them by bad upbringing. In the first class might be included children with certain inborn defects of vision, hearing, and other senses, which made for backwardness, also children physically enfeebled because coming from poor or degenerate stock. As for those who acquired stupidity, he thought that while malnutrition might for the time being depress intelligence, it did not seem to be a cause of backwardness in itself. General diseases likewise did not seem to have a very pronounced influence in this respect except in so far as they led to absence from school. The effect of diseases of the central nervous system was an important and interesting subject. The most obvious of these was epidemic encephalitis, and the effects of this disease largely determined a modification of the definition of mental deficiency in the new Act. He believed this condition demonstrated in an exaggerated form the process which was seen in a much more common condition—namely, chorea. Choreic children, who were often, of course, rheumatic children, were of the highly strung rather than the bright, intelligent type; but it had been well said that the choreic child was jerky in mind just as he was jerky in body, and so he was erratic, inattentive, and lacking in concentration. Enlarged tonsils and adenoids were often blamed for backwardness, but he was rather a sceptic about the wholesale blessings which followed operation for their removal as a mass production performance. Dr. Gordon also dealt with endocrine abnormalities and emotional disturbances in the same connexion. As for the third class of children, those who had stupidity thrust upon them, this was a group with which, as practitioners, they had comparatively little to do, since in this category were included those who had been badly taught and thus deprived of the grounding which was so essential to future progress. Yet although it was not the business of the doctor to criticize the teacher, he ought to keep in mind that the backwardness upon which he was called on to advise might be due to factors not really within his province at all.

Health and Retardation

The question of the backward child figured in several other discussions during the conference. Dr. MILDRED

consistent carrier of *B. typhosus*. All his tests at the gathering ground had been negative.

In a final speech to the tribunal on behalf of the Croydon Division of the B.M.A. and the Local Medical and Panel Committee, Mr. Forbes said that it might have been wise at such a time to have recognized the Local Medical and Panel Committee as a body with which to co-operate. He hoped that medical men would in future be co-opted on the Public Health Committee. Mr. Forbes added:

"My clients are not here to make any attack on anybody. It is apparent to the tribunal, and must be to everybody, that the Croydon medical officer of health is a loyal, able, and industrious servant of the corporation, and it appears also that in the witness box he was a truthful and careful witness. Whatever I have to say by way of criticism of his views, it must not be thought by him or by anybody that it constitutes anything in the nature of an unfriendly attack or an attack of any description."

The Case for the Medical Officer of Health

The closing speech of Mr. P. E. Sandlands, K.C., for the medical officer of health, occupied the whole of one afternoon and the greater part of the next morning. He said that Dr. Holden had been medical officer for Croydon since 1928, and, before that, medical officer for two other important county boroughs. In the letter over the signatures of Lord Dawson and Sir Kaye Le Fleming he was referred to as "distinguished," and Mr. Forbes, counsel for the Croydon Division of the B.M.A., who came to the Inquiry as a critic, ended by being almost a partisan of the medical officer, whom he described as loyal, able, and industrious, and as a witness careful and truthful. The tribunal had seen him in the witness chair, and heard what he had done—or only part of what he had done, because there had been hundreds of duties in connexion with the outbreak which he had efficiently discharged and on which no comment was made—and he could not help feeling that the critical atmosphere in respect to Dr. Holden in which the Inquiry began had been considerably modified as it proceeded. He thought Dr. Holden must have impressed the tribunal with his modest demeanour and quiet efficiency.

What were the causes of the outbreak? Was Dr. Holden blameworthy in failing at first to localize the source or in dealing with it when localized? A medical officer of health had many statutory duties, but no statute had laid upon him the duty of looking after the water. The governing regulation read that "he must inform himself as far as practicable as to all matters affecting or likely to affect public health in the district and be prepared to advise the local authority on them." "As far as practicable" was a phrase like a concertina, which could be extended or compressed. The criterion of judgment was what the medical officer's predecessors had done and what he himself had done. He had never been summoned to the Water Committee. The borough engineer and the medical officer both had service agreements, and it was fair to suppose that the borough engineer was the senior officer; his remuneration indicated this unmistakably. But both were principal officers, and each was under an obligation to let the other know about matters affecting the other department. Dr. Holden in repelling criticism was not seeking to deflect it to anybody else. His impression of Dr. Holden was that he would rather take blame which was not clearly his than let a colleague suffer. He was not attacking the borough engineer or anybody under him. Dr. Holden had no special duty with regard to water, but he had from time to time inspected the gathering ground and had made recommendations to the borough engineer.

The most probable cause of the outbreak was the infection of the Addington well by a carrier working at the well. That was the opinion of Dr. Suckling and Dr. Conybeare. Against that was the opinion of Sir William Willcox that the cause of the outbreak was sewage from the gathering ground getting into the well through

fissures in the chalk, but Sir William had not heard all the evidence. Was Dr. Holden to be held responsible for a carrier? He did not know that work was proceeding at the well. In fact nobody was to blame for this unhappy accident. If a medical officer of health was to be held responsible in such a case eligibility for such an office would require "a combination of the qualities of Solomon, the Archbishop of Canterbury, the heads of the Royal Colleges, and a veterinary surgeon." Dr. Holden had believed that chlorination was in progress. As long ago as 1930 he had suggested that, chlorination of the Addington well should be considered. Mr. Sandlands desired to make it clear that the dose which Dr. Holden had recommended—namely, 0.05 part in a million—was simply a precautionary dose, to be increased when circumstances demanded. To double the dose would make the water more resistant from the point of view of other organisms, but not from the point of view of typhoid; when dealing with the typhoid bacillus the smaller dose was sufficient. The advice Dr. Holden had given with regard to chlorination was perfectly sound and had resulted, as the succession of analyses showed, in a most satisfactory water being supplied until the eve of the outbreak. Mr. Forbes had expressly exonerated Dr. Holden from any blame in this respect, and Sir William Willcox had said that from the scientific point of view the detection of the cause of the epidemic was a very good piece of work and a quick diagnosis.

The chairman said that there was no question of the tribunal differing from what Sir William Willcox had said on that point.

Potential Causes of Outbreak

Mr. Sandlands went on to urge that it was the business of the medical officer, faced with an outbreak, to consider all possible causes; only by elimination could he arrive at the actual source of the trouble. Suppose it had turned out that the infection was milk-borne, and Dr. Holden had from the first concentrated his attention on the water, would he not have been subject to criticism? In fact, five out of the first six cases were on the same milk supply, and, with the Bournemouth epidemic in mind, Dr. Holden was keeping in view the possibility of milk among other causes. But he never neglected the water. It had been stated in evidence that at a meeting of residents, in reply to a question, he said it was "inconceivable" that the water could be to blame, but it was evident that all the people concerned were thinking at that time, not of the general water supply, but of some local contamination affecting the main in the streets where the first cases arose. Even before that meeting took place Dr. Holden, so far from neglecting water, had given instructions for samples to be taken from taps in the houses where cases had occurred and for the mains to be tested.

On the question of want of co-ordination, the fact that no medical committee was in existence might be a matter for recommendation by the tribunal. But it was not a matter on which the medical officer could be expected to take the initiative during an epidemic. It was not Dr. Holden's fault that the committee was not constituted; it was for the other doctors to constitute the committee and proffer their help. He was not concerned with the suggestion that there should be an obligation on all local authorities to set up committees of medical men, but Dr. Holden had said that he would be glad to have co-operated had such a committee existed. Neither the Panel Committee nor the British Medical Association represented the whole of the medical profession, and, moreover, as Sir William Willcox himself had said, the thing could not be done in the midst of an outbreak; it must be prepared beforehand. But he was anxious that the tribunal should not have the impression that the Corporation or Dr. Holden was antagonistic to the idea.

In conclusion Mr. Sandlands hoped the tribunal would not forget the hundreds of things that Dr. Holden had

Reports of Societies

CARDIAC COMPLICATIONS IN MAJOR ABDOMINAL SURGERY

At a meeting of the Section of Surgery of the Royal Society of Medicine on January 5, Professor G. GREY TURNER presiding, the question of cardiac complications in major abdominal surgery was discussed.

Dr. PAUL WOOD said that the cardiac complications of major abdominal surgery were "over-diagnosed" by many surgeons. Hearts with disease stood up to the strain of abdominal operations surprisingly well. During the post-operative period certain symptoms suggested heart trouble. He proceeded to attempt a classification of cardiac and non-cardiac complications based on these presenting symptoms. Pain in the chest might be due to myocardial infarction, to pulmonary embolism, or to pericarditis; more often it was non-cardiac. He laid stress upon the various manifestations of pulmonary embolism, and particularly upon the cases without pain or haemoptysis. Dyspnoea might be caused by congestive heart failure or by pulmonary embolism, but was usually non-cardiac, and might be due to pulmonary complications, to abdominal distension, to subphrenic inflammatory conditions, or to uraemia. He emphasized the rarity of congestive heart failure as a post-operative complication. Sudden collapse might be due to myocardial infarction or to pulmonary embolism. A slower type of collapse was usually due to dehydration, haemorrhage, peritonitis, or to other surgical complications. Peripheral circulatory failure was far more frequent than cardiac failure. A rising pulse rate and a falling blood pressure were important signs of impending collapse, and sufficient fluids must be given rectally or intravenously—about 7 litres in twenty-four hours; a urinary output of some 1,500 c.cm. daily should be maintained. Irregularities of rhythm were commonly due to ectopic beats, and pointed more to infection or to abdominal distension than to heart disease. Patients who developed auricular fibrillation should be thoroughly overhauled by a physician.

He summed up his argument by saying that the most dramatic occurrences were usually due to pulmonary embolism, but might be the result of myocardial infarction. Dyspnoea found alone was nearly always of a pulmonary nature, and might derive from bronchopneumonia or some like condition. Congestive heart failure was a rare event, and did not occur unless the heart was very badly diseased. When faced with obscure post-operative disease the surgeon would do well to consider carefully all possible surgical causes and complications before he accused the heart. In the absence of a necropsy it was often very difficult to convince the surgeon of the heart's innocence.

Cholecystitis and Heart Disease

Mr. D. H. PATEY remarked that it was interesting to hear the cardiologist emphasize the rarity of heart failure as a cause of death after operation; this point had been stressed so much from the anaesthetist's side. He raised a question on the apparent association of the gall-bladder with cardiac pain. Was there some relation between the gall-bladder and myocardial infarction, or was it that cardiac pain was simulated by the gall-bladder? Mr. H. W. RODGERS asked whether the fear of impending death had been found to have any relation to the presence of a cardiac lesion: also whether the use of digitalis was at all justifiable in cases in which there was no auricular fibrillation. Mr. HOPE CARLTON referred to the amount of fluid which Dr. Wood had recommended in cases of impending collapse. It seemed to him that 7 litres in twenty-four hours, given rectally or intravenously, was enormous. Ten years ago intravenous therapy was pressed upon them strongly, but more recently it had been somewhat discounted. Professor GREY TURNER was glad to

find Dr. Wood insisting on the risks that could be taken surgically in cases of heart disease. Nothing had impressed him more than the way in which patients with heart disease would tolerate the necessary operation.

Dr. WOOD, in reply, said that cholecystitis was sometimes diagnosed as angina and angina as cholecystitis. In patients with angina and cholecystitis or gall-stones, if the gall-bladder were removed there was a temporary improvement in the angina. Any failing heart would benefit from digitalis, but if administered it should be by a physician. With regard to fluid, it had been shown quite conclusively that patients needed 6 pints of fluid a day. About half of this amount they received in the form of solid diet; but the patients in these cases were not receiving solid diet, and therefore required the same amount of fluid in another form. In addition, they might have been vomiting a great deal, certainly they had been sweating, and probably over-breathing under the anaesthetic, so that they were in a dehydrated state. He granted that if 7 litres were given in twenty-four hours most of it should be given rectally. Far more fluid could be given successfully by the rectal route than was generally recognized.

The Circulation in Gangrene

Mr. JAMES F. PHILIP gave a demonstration by means of lantern slides of the circulation in gangrene of the lower extremities as seen radiographically after injecting the arterial tree. He discussed the different forms of gangrene seen in diabetes, arteriosclerosis, and thrombo-angiitis obliterans. He believed that no single mode of treatment could be universally successful, and that sympathectomy, physiotherapy, and amputation each had its place in the treatment of this disease. As regards the venous system, in arteriosclerosis the veins were seldom occluded; in diabetes, thrombosis of the veins was a frequent occurrence; and in thrombo-angiitis obliterans the veins appeared to be affected just as much as the arteries. After some questions and brief discussion Professor GREY TURNER said that he could not help thinking that there was yet a good deal of work to be done on revascularization in such cases. It must be assumed that something of this kind might occur in certain cases of gangrene spontaneously. He recalled patients in years gone by who had refused to have surgical intervention in gangrene, and who had recovered. In diabetic gangrene he had been impressed on occasion by the extreme virulence of the infective type. This was not nowadays so often noticed, because the metabolic condition was brought under treatment at an earlier stage.

Mr. PHILIP, in reply, described attempts at revascularization by means of physiotherapy, which, he said, gave good results. He instanced the case of a gamekeeper, aged 60, who could walk only 200 yards before developing claudication. Pulsation was absent from the major arteries of both legs. He was put on various exercises, contrast baths—that is, alternating hot and cold—and diet, with rest and the wearing of warm socks, and afterwards reported at three-monthly intervals. He had now been back at work for three years, though there was some slight recrudescence of the trouble each winter. Even in gangrene due to diabetes these attempts at revascularization of the limb had been at times of assistance.

A meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland was held on December 10, 1937, with the president, Dr. E. T. FREEMAN, in the chair. Dr. H. L. PARKER reported a case of the Laurence-Moon-Biedl syndrome, and Dr. ALAN THOMPSON a case of chloroma. Dr. P. T. O'FARRELL read a paper on a series of cases of both acute and chronic types of peripheral arterial occlusion of organic origin. Each communication provoked a lively discussion in which, among others, Dr. A. R. PARSONS (President of the Academy), Dr. EUPHAN MAXWELL, Dr. E. HARVEY, Dr. G. C. DOCKERAY, Dr. J. C. FLOOD, Dr. H. B. GOULDING, Dr. BOUCHIER HAYES, Dr. J. LEWIS, and Dr. JESSOP took part.

CREAK, psychiatrist at the Maudsley Hospital, discoursed to the Child Guidance Council on the children who fail to learn. Even the Mathematical Association discussed the teaching of the complete duffer, and seemed to agree that mathematics was the first thing to suffer when a child was undergoing emotional conflict. The trouble was, as Dr. F. H. DODD pointed out to the mathematicians, that such a child retreated into a world of fantasy, and the world of reality—which is a mathematical world—became remote.

Dr. CHODAK GREGORY addressed the Child Study Society on "Health and Retardation." In particular she spoke of the neglect of children during the second and third year of life—a period of great morbidity if not of mortality. Advice on behalf of the toddler was comparatively rarely sought, and it appeared to be the idea of many parents that, having weathered the stress of infancy, he could be awarded a little wholesome neglect. Dr. Gregory also said how strongly she had been impressed by the incidence of rickets in young children. She had been asked to judge a baby show in a village, and was horrified to find that when the thirteen babies presented were undressed all but one of them showed some signs of rickets. This was in a village where there was no unemployment and where every cottage had its garden, though it appeared to be the parents' habit to keep their children in the stuffy rooms.

Dr. J. A. HADFIELD, who presided on this occasion, said that in his opinion, in respect of the recognition of mental deficiency at an early stage, council schools were more fortunately placed than private. He had had not infrequently children sent to him with quite aggravated mental deficiency by parents who refused to admit that their children were mentally deficient at all. Often backwardness was due to emotional causes. A child whose whole mind was occupied with fear and anxiety could not be expected to devote himself to scholastic work. Sometimes the fear arose out of a hypersensitive conscience, and in such cases might be traced back to an illness in early childhood. The fact that the child had got over pneumonia, rickets, or some other malady did not mean that everything was well. These conditions often left behind them abnormalities which manifested themselves later in the form of morbid fears.

Many Voices

The spiritual aspect of health, dealt with by Dr. BURNETT RAE before the Institute of Christian Education, attracted one of the largest of the sectional audiences. Fatigue problems in the preparatory school child was the subject of an address by Dr. ANNIS GILLIE to the Association of Head Mistresses, and Dr. BRADFORD HILL of the London School of Hygiene and Tropical Medicine addressed the Association of Teachers of Domestic Subjects on national nutrition. Physical training in the Army was described by Major T. F. KENNEDY to the British Association for Physical Training. The Army system, he said, was a combination of the Swedish and Danish systems, and aimed at producing a harmonious development of body and mind through the medium of progressive muscular-education. The Ling Physical Education Association was addressed by Mr. KENNETH LINDSAY, M.P., Parliamentary Secretary to the Board of Education, on the subject of national fitness, and this body had a number of other speakers, including Mr. W. P. ALEXANDER, director of education for Margate, who criticized the three-year course for physical education instructors on the ground of the insufficiency of time devoted to psychology.

The University of London Animal Welfare Society arranged a lecture by Dr. R. LOVELL of the Royal Veterinary College on diseases common to man and animals. After reviewing the various bacillary and protozoal diseases he showed how a disease in one species might develop in a different way from the same disease in another. A familiar example was the disease due to *Brucella abortus* as manifested in man and in cattle.

Finally a session was devoted to the health of the teacher's voice, which was considered in relation to the health of the individual as a whole. Dr. PHILIP KEMP, school medical officer, Birmingham, said that while the evils of noise had been faced and to some extent remedied, little had been done to exploit the therapeutic value of pleasant sounds. He foresaw a time when appropriate music might figure in medical prescriptions, especially in nervous disorders.

INTERNATIONAL ORGANIZATION AGAINST TRACHOMA

MEETING IN CAIRO

A meeting of the Executive Committee of the International Organization against Trachoma was held on December 9, 1937, at the Semiramis Hotel, Cairo. The secretary-general read the minutes of the previous meeting, held in Paris in 1936, and the accounts were then passed. The subvention given for purposes of research by the American Academy of Ophthalmology and Oto-laryngology—100 dollars—was allocated to Dr. Poleff of the Pasteur Institute at Rabat, Morocco. It was decided to hold the next meeting of the organization at the same place and at the same time as that of the International Council of Ophthalmology, in 1939.

Assembly of Delegates

On the following day an assembly of delegates was held. After a statement by the president on the business to be transacted, the audited accounts were passed, and Professor Manuel Marquez was elected an honorary member of the Executive Committee. The president, Mr. A. F. MacCallan, and the secretary-general, Dr. Wibaut, who were elected for a period of five years at the meeting in London in 1935, remain in office. According to the statutes four members of the Executive Committee were then due to retire, but as all members had to retire in 1937 it was decided to defer elections until the present meeting.

The president explained that six nations were already represented on the Executive Committee, as follows: Great Britain (Mr. MacCallan, president), Holland (Dr. Wibaut, secretary-general), France (Dr. Bailliart) and the United States (Dr. Park Lewis); representing the International Association for the Prevention of Blindness, Hungary (Professor de Groot) and Spain (Professor Marquez); honorary members. For the twelve vacancies it was decided that twelve nations other than those previously mentioned should be represented, and that each national representative should be selected by the national group; also that, as provided in the statutes no distinction should be made as to grades of vice-president, members, and secretary. It was then resolved that the following nations, as being those most subject to trachoma, should be represented on the Executive Committee: Argentina, Bulgaria, Czechoslovakia, Egypt, Germany, India, Italy, Japan, Lithuania, Poland, Rumania, and Turkey. Subsequently it was announced that the national groups had chosen the following as their representatives: Argentina, Dr. José A. Sena; Bulgaria, Professor Pascheff; Czechoslovakia, Professor Kadl; Egypt, Dr. Tewfik; Germany, Professor Rohrschneider; India, Professor Leonardi; Japan, Professor Oguchi; Lithuania, Dr. Avizonis; Poland, Dr. Zuber; Rumania, Professor Michail; Turkey, Dr. Naci Bengisu.

The Scientific Meeting

On December 10, 1937, the scientific meeting was held at the Semiramis Hotel. After an introductory address by the president, interesting discussions were held on "The Biological Aetiology of Trachoma," on "The Pathology of Trachoma," opened by Dr. Roland P. Wilson, and on "The Treatment of Trachoma." These were followed by papers by Professor Motegi, Dr. Iijima, Dr. Zuber, Dr. Naci Bengisu, Dr. Jacobsides, Dr. Hachoua, and Dr. Churruarín.

the middle of the nineteenth century to realize the importance of training in dentistry, and in 1856 he had begun a course of lectures on physiology and diseases of the teeth. Working with others he had opened an Edinburgh Dental Dispensary in Drummond Street in January, 1860. After various transfers the dispensary had come to occupy the present site in 1878, and had changed its name to the Edinburgh Dental Hospital and School. In 1914 the site and premises had been purchased, but the plans for extension had to be postponed till after the war. There had been alterations in 1927, but there was now urgent need for further extension. So far £11,000 has been subscribed in response to the appeal.

ENGLAND AND WALES

Prevention of Blindness

The London County Council is proposing to ask the Medical Research Council to take steps to investigate the question of the influence of myopia in causing blindness and the part played by the special schools for the partially sighted in such prevention. The Hospitals and Medical Services and Education Committees of the County Council have jointly considered the matter, and are of opinion that in order to obtain some satisfactory knowledge of the problems of myopia an investigation is urgently necessary. Such an investigation should be a comprehensive one and could not be adequately undertaken by a local authority. Assistance could be rendered to the Medical Research Council by placing county council records at its disposal and giving facilities for research work to be carried on in its educational institutions. The matter has arisen immediately out of the recent report of the standing committee of the Union of Counties Association for the Blind, a voluntary body working in close association with the Ministry of Health, the Board of Education, and various agencies chiefly concerned with prevention. This committee, in its report, points out that the treatment of visual defects of children attending special schools was dealt with in the report of the Committee on Partially Sighted Children in 1934. In that report no definite conclusion was reached beyond emphasizing the need for further research. The standing committee is in agreement with the conclusion that the influence of myopia in causing blindness, and the part played by the special school in preventing it, is the most important of all problems with regard to myopia which needs further consideration.

St. Mary's Hospitals, Manchester

The report for 1936 of the maternity department of St. Mary's Hospitals, which has been prepared by Dr. R. Newton, reveals that 931 maternity patients were treated in their own homes and 2,545 in the hospital, no fewer than 1,282 being emergency cases. It is interesting to note that of the 1,263 booked cases 1,040 were delivered at or near term, 215 were discharged undelivered, and there were eight abortions, whereas among the emergency cases admitted to the hospital only 627 were delivered at or near term, 335 were discharged undelivered, and there were no fewer than 239 abortions and nine ectopic pregnancies. There were altogether thirty-three maternal deaths, representing a mortality of 1.31 per cent. of the total in-patients, the mortality in booked cases being 0.63 per cent. as compared with 1.99 per cent. in emergency cases. Cases of contracted pelvis numbered 185, in fifty-three of which delivery was by natural forces; Caesarean section was undertaken in fifty-nine cases and induction of labour in fifty-three. The remaining cases were treated by forceps or by version and extraction. There were nine cases of tubal pregnancy, in seven of which rupture had occurred, and one of these patients died. Rupture of the uterus was also responsible for one death in five patients, and among the twenty cases of eclampsia treated during the year there were four deaths.

Correspondence

Use and Abuse of Antiseptics

SIR,—It is to be hoped that the article on this subject by Professor L. P. Garrod and Mr. G. L. Keynes which appeared in your issues of December 18 and December 25, 1937, has been widely read and will have the influence it deserves. I have on several occasions in the past tried to point out some of the defects of common surgical practice in regard to the use of antiseptics, and I am glad to see that the present authors are in almost complete agreement with me.

Greater emphasis might perhaps have been laid on the selective action of some chemical antiseptics. The older ones, such as carbolic acid or the hypochlorites, are more or less equally active on all pathogenic bacteria. Some of those introduced more recently, however, are highly selective, and inhibit the growth of one microbe in very high dilutions while having little effect on another (which may be closely related to the first) in ten, twenty, or more times that concentration. It seems to be the fate of all chemicals that if they are shown to have a beneficial effect on infections by one bacterium they are used in all sorts of other infections, despite definite laboratory evidence that there is no chance of their exercising any influence on the growth of the infective agent.

Wisely, the authors have treated separately the problem of the recently inflicted wound and that of the wound in which the infection has become established. In the recently inflicted wound the bacteria have not grown out but are simply lying at the point at which they were introduced, nor have the tissues begun to react to the infection. Theoretically it should in many cases be possible to reach the bacteria with an antiseptic, but practically in all but clean-cut wounds it has been shown that efficient surgical technique is more effective than chemicals. The body, if given a chance, can deal with considerable numbers of the bacteria which commonly infect wounds, and it is the function of the surgeon to give the body a fair chance. In most cases it is only the less skilful surgeon who would pin his faith on the local application of a chemical. In an established infection the bacteria have grown into the tissues and are out of reach of an antiseptic applied to the surface. At the same time the tissues around have reacted to the infection and are crammed with phagocytes whose function is to ingest and destroy the bacteria.

The injunction of Garrod and Keynes that "strong applications to the wound itself are to be avoided" seems to sum up a reasonable teaching in regard to the use of antiseptics in such wounds. They mention that some antiseptics may give benefit by a mild irritation which stimulates the flow of fluid from the infected walls into the cavity of the wound. This drainage of the infected tissues is as important as the drainage of the cavity of a wound. The defence against a septic infection is mainly phagocytic, but before the bacteria can be picked up by the phagocytes they must be acted on by the opsonic substances in the body fluid. These opsonic substances become used up in the stagnant fluids in the wall of an infected wound, and unless such fluids are drained off and replaced by fresh fluid from the vessels it is clear that the phagocytes are at a disadvantage. The importance of draining the infected tissues is not as well appreciated as it ought to be. However, this is not direct antiseptic action, and if we are to apply the name "antiseptic" to substances which stimulate the outflow

Local News

SCOTLAND

Glasgow Royal Infirmary

The annual nurses prize-giving and tour of the wards of the Royal Infirmary, Glasgow, was made on January 1 by Lord Provost Sir John Stewart and the governors of the institution. Sir John Stewart said that the voluntary hospitals seemed to have increasing difficulties with finance. He had often wondered why the Royal Infirmary had not started wards for paying patients. These had been successful in another hospital in Glasgow, and in the case of the Royal Infirmary would, he thought, help to ease the financial situation. Sir James Macfarlane, chairman of the Governors, said that their expenditure was steadily increasing, and during the past year had gone up by £10,000. Legacies, on the other hand, had dropped by £10,000. Provision had been made for paying patients in an auxiliary hospital of the Royal Infirmary at Canniesburn, which would be opened by Sir Iain Colquhoun on January 18. The number of patients admitted to the Infirmary during the past year had been 18,171—529 more than in the previous year—and the number of out-patients had been 113,003. During the year the hospital had obtained possession of the neighbouring premises previously occupied by the Royal Asylum for the Blind. Part of that building was being altered and would be used to accommodate the outdoor department and make provision for various specialties, including x-ray diagnostic work, medical electricity, and massage.

Maternity Work in Glasgow

The medical report for 1936 of the Glasgow Royal Maternity and Women's Hospital illustrates the working of the "permanent unit system." Of the 175 beds in this maternity hospital seventy-eight are reserved for ante-natal cases and another seventy-eight for lying-in cases, while nineteen beds in a special isolation block are set aside for suspect cases. Septic cases are transferred to the city fever hospitals. During the year under review 4,717 patients were admitted, the average daily number of patients in the wards being 166; the number of children born in the hospital was 3,389. There were sixty-six maternal deaths, the death rate being 1.4 per cent. Joint action with the Glasgow Corporation enabled the hospital to continue its policy of not refusing treatment to any woman in labour and at the same time not further overcrowding the wards. In 1936 the municipal hospitals accepted 651 patients as overflow cases. The ante-natal department is growing in importance; from the ante-natal dispensary on the hospital premises many cases were admitted to the obstetrical department and the ante-natal wards. During the year 4,724 women were attended in their homes by the hospital staff and 4,543 infants were delivered. The number of abnormal cases was 3,346 (70.9 per cent. of all admissions), many being emergencies, a fact which, coupled with the high incidence of rickets in the population served by the hospital, indicates the gravity of some of the cases and has a bearing on the morbidity and mortality rates. Twenty-one patients (31.8 per cent. of the total number of maternal deaths) died within twenty-four hours of admission, and a further twenty-one, who survived that period, died within seven days of admission. Of the total 4,717 cases treated in the hospital wards, 1,864 (39.5 per cent.) had received ante-natal supervision in the hospital clinic. The medical staff is conducting research into infections of the urinary tract, puerperal fever, the toxæmias of pregnancy, and the endocrine glands. This annual report, which has been as ably prepared by the registrar, Dr. R. Murdoch, as its predecessors, contains much information of clinical

interest, including a classification of maternal deaths on a pathological basis, with a detailed summary of each of these cases.

Finance of the Edinburgh Royal Infirmary

At the annual meeting of the Court of Contributors to the Royal Infirmary, Edinburgh, Sir Thomas B. Whitson, chairman of the Board of Managers, referred to a deficit of over £40,000 on the ordinary account for last year's working. There had also been an extraordinary expenditure with additions and improvements to buildings of £15,000, and a sum of £62,000 had to be met from legacies and special donations. The Managers pleaded most earnestly for increased and additional contributions, especially in view of the future, when, with a much larger institution, more expenditure would be incurred. The ordinary expenditure for the year had been £177,044. The average annual cost per occupied bed had been £177, and the average daily cost per patient 9s. 9½d. The speaker suggested that many people might be able to send a ten-shilling note, which would pay for one patient for one day. The appeal for the extension fund, he continued, was not making headway as quickly as they would like. Of the £200,000 appealed for only £80,000 had so far been raised, leaving £120,000 still to be collected. The most strenuous efforts would be required to get that sum.

It was agreed at the meeting to remit the annual report to a special committee for consideration. The report states that one satisfactory feature of the accounts was that the increase in ordinary expenditure had been covered by a corresponding increase in ordinary income, but the Managers could not but feel anxious as to the financial position in view of greater commitments in the future. When it was considered that patients were not asked to contribute, nor was there any inquiry as to their means, the amount received as contributions from patients, £5,407, was not unsatisfactory, but a further increase from this source would be welcomed. There had been a progressive falling off in the payments made by approved societies as additional benefits during the last few years. It was fortunate, however, that the receipts from legacies had been highly satisfactory, amounting to £95,142, of which £14,388 had been bequeathed for endowment purposes. Prices of commodities, as well as the number of patients treated, had risen, and the cost of maintaining the radiological department had reached a figure of £15,000 per annum. New methods of treatment, improved apparatus, and increased arrangements for the care and comfort of patients all created additional expense. The National Radium Commission had allocated to the Infirmary, as the National Radium Centre for South-East Scotland, a further supply in order that the mass unit might be increased to three grammes. The enlarged "bomb" had been erected at Beechmount Annex, and would very shortly be in operation.

Edinburgh Dental Hospital and School

An appeal has been issued by the Edinburgh Dental Hospital and School for £55,000 to meet the growth in the number of patients and the need for more modern accommodation and equipment for teaching and treatment. Lord Provost Gurnley, in a broadcast speech on January 2, said that this was the largest dental school in Scotland, and, in the United Kingdom, was second only to the dental school of Guy's Hospital. Patients attending in 1936 numbered 29,369, and in 1937 that number had risen. There had also been an increase in the number of students; in 1934 there were 187, and in 1937 there were 274. It was now proposed to demolish the old parts of the hospital behind the present modern frontage. These had originally been private houses, and their place would be taken by a building provided with what was practically an all-glass back. The natural lighting would thus be efficient for day work, and for night work special electric lighting would be available. The history of this hospital was interesting. Dr. John Smith had been the first man in Edinburgh to

fever, the chief credit undoubtedly belongs to my sister, Dora Colebrook—with the reservation that her investigation was made possible by the earlier pioneer work on agglutination reactions of haemolytic streptococci by Dochez, Avery, and Lancefield (1919), F. Griffith (1926 and 1935), and others. For the demonstration of the paramount importance of the group A streptococci in connexion with puerperal fever the chief credit belongs to my former colleague Dr. Ronald Hare, here again with due acknowledgment of the earlier work on the differentiation of the haemolytic streptococci into groups by Mrs. Lancefield.—I am, etc.,

Bernhard Baron Memorial Research LEONARD COLEBROOK.
Laboratories, Queen Charlotte's
Maternity Hospital, Jan. 6.

Insulin for Local Sepsis

SIR.—Mr. Nevil Leyton has just recorded (*British Medical Journal*, January 8, p. 70) his great success in healing chronic local sepsis by dressings of ordinary insulin solutions. This is no new story, and similar enthusiasm was recorded in France about 1926 in the treatment of chronic ulcers (I regret that, being in the country, I cannot now give the exact reference). Later it was shown that a dressing of similar acidity and anti-septicity without insulin had the same effect as actual insulin solution. And so the enthusiasm waned to revive again now.

From the nature and physiological action of insulin it is highly improbable that it can have any local action on a raw area. Insulin dressings, particularly of "double-strength" insulin which Mr. Leyton has used, must be very expensive, and before the method is advocated for widespread use more controlled and convincing experiences must be available. I would suggest that half the wound be dressed with active insulin solution, the other half with heated—and so inactivated—insulin solution. If any difference in healing is observed the expense might be proved worth while.—I am, etc.,

London, W.1, Jan. 10.

R. D. LAWRENCE.

Names for New Drugs

SIR.—During the past two years three groups of drugs, which may fairly be said to have revolutionized treatment in their respective spheres, have been widely introduced into medicine. It seems to me regrettable that while some of them have become the subject of a terminological haze, others are not yet easily available. The value of the sulphonamide or "prontosil" group must surely have been appreciated in view of its constant mention in recent literature, but it is still only possible to prescribe drugs of this group under a simple and easily remembered name by having recourse to proprietary preparations. It must be the experience of many panel practitioners that the price of these preparations varies greatly, and in the event of his prescribing honestly for his patient, and at the same time reducing the cost of his prescription to a minimum, he is always liable to end up with a headache. Since in the long run the true value of any drug rests in its successful use in the treatment of disease, and as the greatest incidence of disease in this country falls among the insured classes, the subject would seem not unworthy of a Royal Commission.

In my experience it may be fairly stated that the treatment of *B. coli* urinary infections has been revolutionized by the use of the mandelic acid derivatives. The period of illness and probably the liability to residual infection have been greatly diminished by these drugs. Is it any longer

fair to the insured classes to prolong treatment by using the less effective but inexpensive alkalis and hexamine medication? The cost of a prescription containing ammonium mandelate is high, but if the compensation paid to the patient while off duty were taken into account, the ultimate expense to the national health insurance funds would probably be less. Is it too much to ask that this drug should be included in the national health insurance formulary as soon as possible? Lastly, cannot some effort be made to create standard names for the more effective hormone preparations, in view of their increased efficacy and decreased cost? The trade names of these are rapidly becoming legion, and seem to me again to have outgrown the realms of easy reference. I feel that these deficiencies might in some way be overcome for the benefit of the general practitioner, among whose cases most opportunities for the exhibition of the drugs occur.—I am, etc.,

Grangemouth, Scotland, Jan. 4. J. M. HENDERSON, M.B.

Bacillary Dysentery

SIR.—Dr. Reginald Miller's paper on Sonne dysentery in the *Journal* of January 8 (p. 64) is a timely reminder that bacillary dysentery is endemic in this country, contrary to general belief. It is comparatively common in villages in agricultural districts where domestic wells and earth closets are the rule; and it is not unusual to find from time to time that diarrhoea "goes through the village." These cases present in a mild degree the usual dysentery syndrome of colic, frequent stools, passage of blood and mucus, and tenesmus, and over and over again I have found them to be associated with one or other of the dysentery bacilli. I have no doubt that a number of them are later diagnosed as "ulcerative colitis" because their original nature has been unrecognized, appropriate treatment has been lacking, and the patients have become secondarily infected. Moreover, they have never "been abroad."

The causative organism may, and does, vary in kind and virulence in different epidemics. Fortunately in this country it is the exception for the virulence to be of a high order: yet it will be recalled that a number of deaths occurred during recent drought years and that several members of one family died near Wantage from drinking water taken from the River Lambourne. Flexner Y was isolated.

The degree of severity depends doubtless on the virulence of the particular strain of organism concerned and the degree of immunity of the individual; but, as is well known, it varies within wide limits. At one end of the scale slight abdominal discomfort and the passage of one or two loose stools: at the other, death from toxæmia before the patient has passed a single typical dysenteric stool. I have seen *Bact. shigae* isolated from a comparatively mild case and *Bact. sonnei* from one of much severity. The more I see of it the less do I feel inclined on clinical grounds alone to associate any particular organism with a "clinical type." The dysentery syndrome indicates an acute infective ulcerative colitis—and that is about as far as it is safe to go on purely clinical grounds without guessing.

With regard to the vomiting mentioned by Dr. Miller, may I suggest that this may be purely toxæmic? After a day or two more or less ketosis is sure to be present; and if acetone be not noticeable in the breath ketone bodies will be found in the urine, due to starvation. Whether in the presence of toxæmia this is as harmless as uncomplicated starvation-ketosis I am not prepared to

of fluid from the infected walls of a wound, then common salt would have to be classed as a potent antiseptic, for this increased outflow is the basis of the hypertonic salt treatment which has been shown to be of great value in the treatment of septic wounds. Garrod and Keynes confirm my finding that Dakin's fluid has this power of stimulating the outflow of fluid from the walls of a wound. They mention continuous irrigation with this fluid, but this procedure does not seem to be necessary; better results were, I believe, achieved by the intermittent irrigation introduced by Carrel when Dakin's fluid was instilled into the wound every two hours. I have shown that within ten minutes of placing Dakin's fluid in a wound it ceases to be antiseptic in a serous medium. In Carrel's method, therefore, the antiseptic functions as an antiseptic for less than ten minutes, but the increased exudation from the walls of the wound persists, so that for something like one hour and fifty minutes out of every two hours there is an increased tissue drainage which favours phagocytosis but no chemical antiseptic that might hinder this defensive mechanism. This treatment was, I think, regarded as the most successful "antiseptic" treatment evolved during the great war.

I should like to make some reference to the action of acriflavine. Garrod and Keynes mention that leucocytes retain motility in a 1 in 1,000 solution. This is true, but in this matter the time factor is all-important. Acriflavine is a slow-acting antiseptic, and its full effect on bacteria is only seen after they have been exposed to the action of the chemical for some hours. Exactly the same thing happens with leucocytes; if only fifteen minutes' exposure is given they retain their phagocytic power in a concentration of 1 in 1,000. If the exposure is five hours their phagocytic activity is seriously impaired by a dilution of 1 in 500,000, and if they are exposed to acriflavine for twenty-four hours they are destroyed by 1 in 2 million—a dilution which has no action on the growth of bacteria.

The best simple test of the probable value of a chemical as an agent for killing bacteria in the body is a comparison of its power of inhibiting the growth of bacteria and of destroying leucocytic function. Such a test will show that all the commonly used antiseptics are more powerful inhibitors of leucocytes than they are of bacteria, indicating that there is little likelihood that by their continuous application any direct beneficial antibacterial effect will ensue. Some of the arsenic preparations, such as novarsenobillon, act on haemolytic streptococci in about the same dilutions as those in which they affect leucocytes, and sulphanilamide only inhibits leucocytes in a dilution of about 1 in 400, while it inhibits haemolytic streptococci in blood in a dilution of about 1 in 400,000. Sulphanilamide and the allied chemicals are the only chemotherapeutic agents which have a much greater action on bacteria than they have on leucocytes, and they are the only chemotherapeutic agents which have been used with striking success for the destruction of the ordinary pyogenic bacteria in the human body.

In conclusion, while congratulating Professor Garrod and Mr. Keynes on their article, I would like to say that my remarks are not in criticism but in amplification of their all-too-short paper.—I am, etc.,

ALEXANDER FLEMING.

Inoculation Department,
St. Mary's Hospital, Jan. 5.

SIR.—The object of this letter is to repair what I think is an important omission in the interesting paper on antiseptics by Professor L. P. Garrod and Mr. Geoffrey L. Keynes. Briefly stated, their paper deals with anti-

septics applied as lotions. Areas in which suppuration is kept up by the irritation of infected discharge are frequently treated by these. Any penetration of the antiseptic which takes place depends on diffusion, and unless the conditions are favourable penetration is slow and, moreover, is not easily controlled. The writers point out that the strength of solutions must be moderate to avoid causing irritation or destruction of tissues. The omission is that no mention is made of the electric current for introducing a particular component of a salt in solution which is a recognized antiseptic, such as zinc sulphate. The component in it on which the antiseptic action depends is the zinc ion. The solution can be used so weak (0.25 per cent.) that penetration due to diffusion need not be considered. The penetration and its extent depend on the strength of the electric current and on the time this is applied. When introduced the zinc combines with the albumin present in the film of infected discharge adhering to the surface and in the superficial tissue cells to form zinc albuminate—an insoluble precipitate. This is a bad culture medium for micro-organisms, which therefore die, irritation vanishing and suppuration ceasing. One treatment when the suppurating area is accessible is usually sufficient. The authors do not state how often the antiseptics they mention should be applied, or for how long. This may be due to lack of sufficient convenient clinical material to carry out tests. There exist numerous cases of chronic otorrhoea due to sepsis alone in an accessible position—the tympanic cavity—and the result of treatment by antiseptic solutions would show their relative value and the best method of applying them.—I am, etc.,

Sidmouth, Jan. 3.

A. R. FRIEL.

Prevention of Puerperal Fever

SIR.—May I be allowed to correct a false impression which Professor Miles H. Phillips has conveyed—unwittingly, I think—in his valuable historical review of steps in the prevention of puerperal fever, published in the *Journal* of January 1 (p. 1). He speaks of "special recognition" being given to my work in that field. I want to make it clear that the work done in this laboratory has been essentially team work by all the members of the laboratory staff, and that my own has not been the most important contribution to it. The results of our work may be briefly summarized as follows. First, we were able to confirm the fact, so ably brought out by Schottmüller twenty years ago, that anaerobic streptococci play an important, although not the most important, part in puerperal infections. Secondly, in collaboration with Mrs. Lancefield at the Rockefeller Institute, we were able to show that the great majority of the most severe puerperal infections are caused by one class of haemolytic streptococci, now commonly known as group A, in distinction to the several other groups, and that this, the most dangerous streptococcus, is probably always introduced into the genital tract from some outside source. Finally, it was shown that the haemolytic streptococci causing these severe puerperal infections were in most cases identical with those present in the respiratory tract of some person, with whom the mother was in contact either before, during, or after her confinement. This finding leaves little room for doubt that these streptococci are usually conveyed to the mother from such an extra-genital source.

For this last accomplishment, perhaps the most important landmark in the history of the prevention of puerperal

admitting that there are others who will be very difficult indeed and who had better be sent to a doctor with special experience. We do, however, need to emphasize the fact that a large number are easily curable, and that the general practitioner should not hesitate to make the attempt. After all, a very large number of those now practising psychotherapy in this country began to do so when they were general practitioners, stimulated and guided by the pioneers, two of whom were mentioned in my previous letter (December 18, p. 1247).

It is indeed important that the doctor in charge of the clinic should not be overwhelmed by crowds of patients, but I do not think he is going to be helped very much by the deliberations of a committee. Such a body is more likely to put the subject to sleep. It would no doubt have many meetings, hear many witnesses, make some recommendations which would receive careful consideration, *et voilà tout*. I think that the doctors in charge of a clinic could do much more to help themselves. As Dr. Skinner points out, I stipulated for one clear hour at the first interview. I shall now ask for another clear hour for the second, and for many patients a third hour at the third interview. If the patient needs any more full hours his case is not a simple one; it may even be an incurable one, for there are incurable neuroses. It seems to me that at the present stage we should concentrate on the easily curable cases, for we ought to demonstrate to the unconverted members of the profession, especially to the teachers, that psychotherapy is worth while, and we shall only do this by curing a large number of patients. There are many important physicians and surgeons who do not yet believe that our labours are of much value for the present or of promise for the future.

I have asked for three clear hours at least for each patient. If the doctor is to have half a dozen new patients sent to him every time he comes to the clinic the thing cannot be done; yet the demand for these hours is not unreasonable. It is clear that every psychotherapeutic interview is, in respect of time consumption, as great an undertaking as an average surgical operation, and in my opinion it is as grave and important a procedure. If a surgeon were told every time he came to his clinic that he was to do six extra operations before he left, in addition to the work he had already planned out for himself, he would, I think, refuse to try. It seems to me that the doctor in charge of the neurosis clinic should explain to his colleagues that it is not only useless but often damaging to see a neurotic patient for a short period, and if his list is full he should say that he is sorry he cannot see another patient until he has cleared off those on it. This will create a waiting list for the department, and when, as is inevitable, it becomes a scandal because of its length, his colleagues who wish their patients to receive psychotherapy will agitate to have the staff of the department increased in numbers. So long as this department continues to allow itself to be a dump where every patient who is a bit of a nuisance to the physicians and surgeons can be sent and forgotten, nothing will be done. But if the department will stand up to the others something will be attempted. Back pressure of this kind will do more to bring about reform than any number of recommendations from some committee which has investigated the subject.

I do not think that three clear hours for one patient is too much to ask of the general practitioner; as things are, he spends more time than this on each of his neurotic patients in the course of a year. Dr. Skinner may feel that I have thrown overboard the patient whose case will take a long time. That most of us will have such cases

is certain, but I think that until he has sufficiently impressed his colleagues and his board of management with the importance of his department he must confine himself to two or three long cases, and the others must await their turn until he is free. It is by such methods that the great masters have forced their views on the profession. Lister did not call for committees—he just went on demonstrating that his patients did not get septic fevers. We should, I think, do likewise.—I am, etc.,

London, W.1, Jan. 3.

T. A. ROSS.

Early Diagnosis of Pulmonary Tuberculosis

SIR.—In the *Journal* of December 4, 1937, Dr. Geoffrey Marshall, in his address on the early diagnosis of pulmonary tuberculosis, refers to the tuberculin test both for humans and beasts, but does not state specifically what he means by the tuberculin test. For the last few years I have been puzzled as to why there should be so much confusion concerning the usefulness of tuberculin in testing for early phthisis as well as in treatment, and I have concluded that it must be partly due to the use of the Mantoux test only. This in itself is useless for detecting the presence of early and active tuberculous infection. The tuberculin test for diagnosing active infection, as I understand it, consists of the primary intradermal (Mantoux) test followed by subcutaneous injections of increasing strengths, up to 0.01 c.cm., every three or four days, the increases depending upon the degree of reaction obtained with the intradermal injection. Should a diagnostic rise of temperature follow with doses of less than 0.01 c.cm., then further injections are not necessary. It is not a *sine qua non* that an active case should give a positive Mantoux test, and the use of tuberculin is not as simple as it may appear. The late Dr. Robert Carswell always claimed that tuberculin had never really been tried out. In "Further Notes on Tuberculin" (*Medical Officer*, May 15, 1937) two cases are recorded, "A. C." and "W. R.," illustrating a negative and positive tuberculin test. "C. W." is a third case illustrating a positive reaction confirmed microscopically. For those interested in the use of tuberculin the table (p. 61) in *Tuberculin, its Vindication by Technique*, by A. Camac Wilkinson, should be of particular interest and value; also Dr. R. Carswell's article in the *British Medical Journal* of May 16, 1936 (p. 990), on the value of the negative subcutaneous tuberculin test.—I am, etc.,

West Wickham, Kent, Jan. 1.

H. S. BURNELL-JONES.

Sulphonamide-P in *Brucella abortus* Infection

SIR.—The following case may be of interest.

On November 5, 1937, I saw an insurance agent, aged 33, who complained of having had "shivers" and of being unwell for the last three days. He had a temperature of 101.6° F., a pulse rate of 90 and a respiration rate of 22, but there were no other physical signs of disease. During the next few days he developed a slight cough, and his temperature ranged from 98° F. in the morning to 103° F. in the evening.

On the tenth day of the illness I put him on two 7½-grain tablets of sulphonamide-P (B.D.H.) four-hourly. The next day his spleen was palpable, and his post-pharyngeal wall was red and granular. On the twelfth day his blood agglutinated *Brucella abortus* 1:12,500 and *Brucella melitensis* 1:2,500, but was negative against typhoid and paratyphoid A and B. His temperature, pulse, and respiration were now normal. On the thirteenth day I ceased giving him sulphonamide-P, after he had taken in all twelve 7½-grain tablets. From then to the seventeenth day his temperature varied from 98° F. in the

say. Thirst is a common symptom, and in children especially I prefer to give some form of effervescing saline *ad lib*. This should be given when the effervescence has subsided. It relieves nausea and vomiting, corrects ketosis, and, most important of all, promotes elimination of toxins by bowels and kidneys as well as supplying fluid. In children this and repeated small doses of colloidal kaolin will be found adequate for ordinary cases. It is always important to identify the organism at the earliest possible moment in case antiserum might be necessary. The great bulk of a polyvalent serum makes its use very undesirable. From my own limited experience of the dysenteries I should say that Dr. Miller need not fear dehydration. Although the stools may be uncountable they are scanty and mucoid, not profuse and watery as in cholera. If he has any doubt about its determination of the specific gravity of the blood by Rogers' method is simple and will settle the matter.

As regards clinical diagnosis, I think the points are: (a) the epidemic character, (b) the rise of temperature, and (c) the dysentery syndrome. An uncomplicated dysentery should never be confounded with an intussusception; but in a child with bacillary dysentery intussusception might occur very rarely. Dysenteric ulceration may, of course, occur in the appendix. Fortunately it is the common things which usually happen. The abdominal type of subtertian malaria need not be considered in England. A brief microscopical examination of the cellular contents of the stool, pending cultivation or agglutination, will be found very informative.

I am glad to see that Dr. Miller emphasizes the need for rapid cultivation of the stools. If sent through the post they are quite likely to give a negative result. It is worth mentioning that specimens emulsified with glycerinsaline may remain active and culturable even if left in the laboratory over the week-end. In conclusion, I am sorry Dr. Miller did not give us fuller details of the way he feeds his patients, in view of its great importance. They often express a desire for food long before it is safe for them to have it.—I am, etc.,

H. M. STANLEY TURNER.

Ashtead, Surrey, Jan. 8.

SIR,—The article by my friend Dr. Reginald Miller on Sonne dysentery contains some remarks on treatment which may give rise to comment. He dismisses the use of sulphates with barely veiled contempt, although I had felt that the use of these salts was based on a reasonable attempt to understand the pathology of the disorder, the physiological activity of the colon, and the pharmacological action of these remedies.

The treatment he advocates is similar to a method recommended in dealing with cholera about 1850—a method which my C.O. in 1918 suggested that I might try when confronted with a small cholera epidemic. Chalk was then used in place of the more modern kaolin, combined with opiates. The anus was plugged with linen and a tight T-bandage applied. Needless to say we did not use this method but conformed to the usual routine with intravenous salines. I should be sorry to see the use of sulphates abandoned for the scanty reasons put forward by Dr. Miller.—I am, etc.,

London, W.1, Jan. 9.

PEARSE WILLIAMS.

Haematocolpos

SIR,—I was interested in Dr. A. L. Craddock's letter (December 25, 1937, p. 1304), and thought, as I saw a great number of these cases during my twenty-three years in Calcutta, my experience might be of help. My opinion

is that they are never due to hymeneal blocks, but to failure in development of the Müllerian duct. This can be proved by microscopical section of the blocking membrane, for on its inner surface there is always columnar epithelium, whereas on the outer surface it is stratified. These cases can be divided into (1) haematocolpos; (2) haematocolpos plus haematocervix; (3) haematocolpos plus haematocervix plus haematometra; (4) haematocolpos plus haematocervix plus haematometra plus haematosalpinx; (5) haematocolpos plus haematocervix plus haematometra plus haematosalpinx plus haematoperitoneum. The important point is to determine under evipan or general anaesthesia by rectal and abdominal examination whether a haematometra exists with or without haematosalpinx, for if such is the case and the ordinary vaginal incision of the occluding membrane is effected there is a grave risk of organisms growing on a perfect medium, spreading upwards, and invading the tubes and peritoneum, leading to fatal peritonitis. Unfortunately I have seen this occur in six cases where the membrane was, shall we say, haphazardly cut for drainage. Therefore if one suspects this condition it is better to open the abdomen. If the tubes are full of blood they may be clamped at the uterine end, and then an assistant incises the membrane from below, and slow drainage occurs, which can be aided by intra-abdominal pressure; when the uterus has been emptied the sponge-holding clamps are removed and the tubes are milked empty into the uterus.

The whole object of this technique is to make sure that the tubes are completely empty of blood, for if they are perchance distended and the uterus alone is evacuated it is almost a certainty that the fluid will become infected, giving rise to an acute pyosalpinx, with infection of the peritoneum should a leak have occurred through the fimbria to the peritoneum, possibly resulting in death. There is just one more point, and that is that should the occluding membrane be merely opened from below, every care should be taken that no pressure on the abdomen is made, for should such a pressure be made and relaxed there is danger of suction of air into the cavity, perhaps carrying organisms. No douching should be permitted in any circumstances. In this country these cases of major degree are not so often seen as in the Tropics, as mothers more readily seek early advice. During the last four years I have had only five cases in hospital, and in one only was there haematometra present.

Should there be great distension of the tubes it is probable that conception will never occur, and some writers have advocated salpingectomy.—I am, etc.,

V. B. GREEN-ARMYTAGLE.

London, W.1, Jan. 4.

Treatment of Psychoneuroses

SIR,—The thanks of those interested in psychotherapy are due to Dr. E. Fretson Skinner for his handsome acknowledgment (*Journal*, January 1, p. 42) that his first letter (December 11, 1937, p. 1196) did contain some exaggerations. I agree with him that it is undesirable that this correspondence should become a debate on the merits of rival methods of treatment, and that it should, if possible, be confined to the two questions which he has set forth—namely, how to prevent undue pressure on the staff of the neurosis clinic, and how the general practitioner can be induced to deal with at least some of his neurotic patients. He will do this only when we have demonstrated to him that a large proportion of these patients are not difficult to treat, while at the same time

January 1 dealt with purely educational matters; but the present problem is economic as well as educational, for it has been shown that financial difficulties are a greater bar to men obtaining their M.B., B.S. degree than are intellectual difficulties. These economic matters are of no interest to the Universities of Oxford and Cambridge, and for that matter they are really of no interest to the Royal Colleges and the Society of Apothecaries, who would doubtless rather be left alone. On the other hand the University finds that the relative ease with which their undergraduates can obtain a qualification by way of the Conjoint Board affects materially the number who obtain a degree and, therefore, consultation with the Royal Colleges seems advisable. Your correspondents object to this on the grounds that these colleges are not teaching bodies and "can make little contribution to the solution of an educational problem." It would be interesting to know how they differ from the External side of the University of which Sir Ernest is the champion. Perhaps in Professor Greenwood's objection one can get a glimpse of the Academic Jekyll in the rather cynical External Hyde.

I venture to suggest, Sir, that the position in London is most uneconomic. We have two sets of final examinations conducted on more or less parallel lines, both of which cost a lot of money; we have two sets of examiners, busy men who often find that long hours of examining interfere seriously with their work and their teaching; we have the majority of London students sitting for the same type of examination twice over; and we have their parents paying for a double set of examinations. I believe personally that these two examinations should be merged into one, the standard being different for the Conjoint and University students. I cannot but believe that if some such scheme were introduced most of our difficulties would be surmounted. If Sir Ernest Graham-Little's and Professor Greenwood's view prevails we shall still see half our students without their degree, and the Royal Colleges will continue to increase those profits to which Professor Greenwood takes such objection.—I am, etc.,

London, W.1, Jan. 8.

A. M. H. GRAY.

SIR,—This matter has interested me intensely for many years. As a member of the Standing Committee of Convocation (in the Faculty of Medicine) since 1927, and more recently as Bedell of Convocation, I have maintained close touch with my "alma mater" since graduating in 1924.

I have read with great interest the letters in your issues of December 25 and January 1 by Dr. A. M. H. Gray and Professor M. Greenwood; also the articles in the *Lancet* of October 23, and in *St. Bartholomew's Hospital Reports* (referred to by the *Lancet*) by Mr. W. Girling Ball. May I also remind your readers of the valuable correspondence on the same subject which appeared in your columns in November and December, 1934, in which Sir Ernest Graham-Little took part. When it is realized that of all the matriculated medical students in the University of London who pass their second M.B., Part II (equal to the Oxford and Cambridge B.A. and M.A.), only some 54 per cent. ever actually become graduates in medicine and secure the valuable M.B. degree, surely that is a scandal? After six years of study more men should actually become university graduates, with graduates' privileges, as opposed to mere diplomates. If possible, all should be graduates. The great majority of men who enter the medical schools of the London hospitals do so in order to get qualified, be able to practise, and earn a living, not merely in order to fulfil various academic

regulations and to satisfy the academic pundits. There can be little doubt that the final M.R.C.S.Eng. examination is as sound a final qualifying test on the surgical side as anyone could wish for. I believe the M.R.C.S.Eng. is as good as any B.Ch. in the world. The London B.S. is a little harder on the surgical pathology side. It can scarcely be denied that there is a great difference between the standard of the men who just scrape through the Conjoint Board final and the men who satisfy the examiners at the M.B., B.S. Lond. final, and it would be impossible to hand out the London degrees to men who just passed the Conjoint. But surely it is absurd to be running two completely different final examinations in London—the Conjoint Board and the University—putting men to the double expense of 40 guineas for the Conjoint diplomas and 28 guineas for the University degrees?

My proposal is that a wide view should be taken of the whole matter: I believe the Colleges would recognize the cause of education and the needs of the student to be above that of mere money-making. I suggest that there be *one final examination in medicine* in London, with an extra part for the degree men. Students who had passed all the earlier Conjoint Board examinations would be pure Conjoint men, and in passing the new final examination would get their M.R.C.S., L.R.C.P. diplomas; on the other hand, the matriculated University of London students, who had only passed the second M.B., Part II, would get the Conjoint diplomas upon passing the ordinary new final examination, but would have to pass an extra part, in medicine and pathology, in order to get the M.B., B.S. degrees. It is in medicine and pathology that the main difference lies between the degree and diploma standards. Thus, three-quarters of the final test would be the same for all. An arrangement as to fees would have to be reached by the two bodies. It is the fact that, even when the Conjoint diplomas have been secured, an entire new final examination has to be taken in order to secure the M.B., B.S. degrees that causes many men to give it up altogether. Many men are by then doing house appointments. If when the Conjoint final had been passed three-quarters of the London final was also disposed of the great majority would complete the M.B., B.S. final by taking the extra quarter.—I am, etc.,

Lincoln, Jan. 3.

CHARLES A. H. FRANKLYN, M.D.,
B.S., M.R.C.S.

West London Hospital Medical School

SIR,—In your issue of December 25 (p. 1305) "Cambridge Woman Graduate" puts forward a plea for the undergraduate members of her own university who find themselves at a disadvantage, compared with their London sisters, in obtaining entry into the London medical schools. At the present moment we have had some twelve applications from Cambridge women, and all of these have been accepted. As this represents practically half a normal year's entry, I think we can plead not guilty to any charge of discriminating against Cambridge women; moreover, we have also accepted a number of women from that older and more enlightened university which admits women to all the privileges of membership.

In the *Journal* of January 8 Dr. Eva McCall draws attention to the paucity of hospital appointments open to women medical graduates. The West London Hospital will, before long, be in a position to offer at any rate a partial solution to this difficulty. In the article which appeared in the *Journal* on December 4 (p. 1124) it was pointed out that both resident and honorary appointments

morning to 99.4° F. in the evening. On the fifteenth day his spleen could no longer be felt. On the seventeenth day his evening temperature rose to 100.4° F., but after the nineteenth day, when his spleen again became just palpable, it did not rise above normal. I continued to record it night and morning until December 31. He was allowed up on the twenty-fourth day, and has now resumed his work.

Dr. Manson-Bahr, writing in Hutchison's *Index of Treatment* (tenth edition, p. 954) of infections by *Brucella abortus* and *Brucella melitensis*, says: "Treatment is essentially symptomatic. Quinine, salicylates, and antipyretics are often used, but have no action beyond the temporary relief of the symptoms in some instances, and as the disease runs a most protracted course the use of such drugs cannot be persisted in." The case I record is an instance of a heavy infection in which the fever settled down in nineteen days after one abortive relapse on the seventeenth day. There are many possible ways of explaining the shortness of the illness of this young man, but I would suggest that sulphonamide be given a trial in such cases of infection by those who meet them more often than I do.—I am, etc.,

Llandilo, Jan. 4.

J. H. LLOYD.

Treatment of the Common Cold

Sir,—During the past seven years I have experimented with every new treatment in an endeavour to find a cure for the common cold. I long ago came to the conclusion that for a remedy to be of value in the treatment of this condition it must (1) be simple to administer; (2) act within twenty-four hours; (3) not restrict or inconvenience the patient; and (4) prevent the unpleasant sequelae of nasal catarrh, cough, and expectoration. It occurred to me that prontosil album might have some beneficial effect on such a mixed infection as the common cold. Consequently I began to try out the treatment some three months ago on members of my own family. The results were dramatic, so I proceeded to treat patients in my practice, and have to date just over 100 cases treated within the first forty-eight hours of developing a cold. The infections were of a varied nature—rhinitis, laryngitis, cough, etc.—some with slight pyrexia and some with gastric disturbances. In all cases the results were swift, positive, and, in those cases treated in the prodromal stage, most dramatic. The colds were aborted and sequelae prevented. I have not one failure to record so far. The only unpleasant effect noted was that about half the patients complained of slight general malaise while taking the drug, but all agreed that this lasted but a few hours and was infinitely to be preferred to the cold.

I give one 7½-grain tablet of prontosil album at 6 p.m. and two more tablets on retiring on the first day of the cold. Usually this is all that is necessary, especially if the cold is in the prodromal stage. This treatment is given fasting from two hours before the first tablet is taken until two hours after the next two tablets. In the case of a well-developed cold one further tablet is necessary the following night, and should be taken two hours after a meal. In any event a maximum of thirty-six hours usually sees the patient perfectly well. The dose that I have found well tolerated by children weighing over 5 stone is one tablet at night and one the following morning. For children over 3 and under 5 stone half a tablet night and morning, once only, is given. I have not treated any child smaller than this. I feel that my results at least justify further investigation.—I am, etc.,

London, W.7, Jan. 4.

MICHAEL ELYAN.

The Problem of the Final M.B., B.S. Lond.

Sir,—I felt sure that Mr. Mitchiner was not himself responsible for the publication of my name on the document issued by the London Graduates Association and willingly accept his assurance that no discourtesy was intended to anyone who, like myself, might disagree with the association's manifesto.

Sir Ernest Graham-Little has raised a number of points in his letter which require an answer. It is perfectly true that I told him that I intended to support Mr. Mitchiner, even though his views differed from mine. I can still pray for his conversion, an exercise which would be waste of time in Sir Ernest's case. His memory is at fault, however, when he states that I made no protest to him regarding the inclusion of my name in the list of nominations.

I must thank him for correcting one of my statements. I should have said Court instead of Universities Grant Committee. I have, of course, no official knowledge of how the Court's attention was drawn to the small number of students in medical schools who take a university degree. I am, however, indebted to Sir Ernest for quoting the statement of the Court to the Senate, for it makes the position clear, but I would demur to the suggestion that the Board of the Faculty had "flouted the advice of the Court." The Court did not "advise" the Senate, it merely expressed a hope. It is because this "hope" is unlikely to be fulfilled that the Board of the Faculty recommended the Senate to consider other methods.

Sir Ernest accuses me of wishing to degrade the final University examination to the level of the Conjoint diploma. What I have done is to support the report of the Board of the Faculty of Medicine, which reads as follows:

"The Faculty Board agreed that it is desirable that a greater number of students should obtain the M.B., B.S. degrees than has been the case in the past, but that the standard of the degrees must be firmly maintained." (The italics are mine.) "They think, however, that the possibility of devising an alternative mode of approach to the degrees should be explored, and that with this end in view the University might co-operate with the Royal Colleges of Physicians and Surgeons."

I should have thought it would be obvious that the "hope" of the Court could only be realized, under present conditions, by making the new syllabus of a standard comparable to that of the Conjoint diploma, and this the Board of the Faculty cannot recommend.

Sir Ernest states that the "competition of a lower qualifying examination (that is, the Conjoint Board) has become less serious in the last few years." It would be interesting to know on what grounds he makes this statement. It has been shown that only about 8 per cent. of London University students who have passed the second M.B. qualify by the M.B., B.S. examination only. This does not suggest much lessening in competition. To support his statement he quotes figures to show the increased entry of London University students into the medical schools. What bearing this has on his argument is difficult to see. On the other hand, it makes it imperative for those who induce students to enter for the University course to see that they have a reasonable chance of obtaining a degree in the long run.

No one can be more severe on anyone who introduced an irrelevant matter into a discussion than Professor Greenwood, and no one can be more skilled than he in obscuring an issue by the introduction of matters only very faintly relevant to the subject under discussion. The Council Conference to which he refers in his letter published in

"If it had not been essential for the dairy trade of to-day (a series of large combines collecting milks of various ages over a wide area) to find some system whereby they could ensure delivery to the consumer in a sweet condition, it would appear doubtful that general pasteurization of milk would ever have come to the fore. There are many types of pasteurizing plants in operation to-day, both under licence and otherwise, but it seems doubtful whether every pint of milk treated is pasteurized in the true meaning of the word. Under the Special Designations Order the milk has to be held at a temperature of not less than 145° F. and not more than 150° F. for a period of half an hour. This gives a temperature range of five degrees. Actually in practice there is not this margin, as the trade problem of the 'cream line' causes strong opposition from the average dairyman to a temperature exceeding 148° F. Thus in practice the margin is three degrees. Some plants have a heat loss of two and a half degrees. Under these conditions the plant has to be truly efficient and the human element almost perfect to achieve true pasteurization. In checking the temperatures recorded, the fact that thermographs are exceedingly delicate instruments must not be lost sight of. Unless the thermographs are constantly and regularly corrected the temperatures recorded will be found to be misleading. Most systems of pasteurization involve the use of comparatively long lengths of pipe lines. Unless these can be effectively sterilized the milk becomes contaminated after pasteurization."

Under these circumstances it would appear that the day of universal pasteurization has not yet arrived, and that if a compulsory scheme were put into operation there would undoubtedly be a false sense of security.—I am, etc.,

Letchworth, Jan. 5.

NORMAN MACFADYEN.

Correct Footwear

SIR,—The considerable correspondence on this subject in recent numbers of the *Journal* emphasizes its importance in the treatment of many disabilities. In a letter which you published nine years ago (March 30, 1929) I mentioned that nearly thirty years previously I had purchased boots of the correct shape from the firm of Holden Brothers, whose business then had been transferred to Messrs. Holland and Son of London. As Dr. T. Hare has stated, socks and stockings also need supervision as to size and shape, and especially is this the case with children, whose socks, shrunk by frequent washing, become so small that the effort required for their removal is very evident, and the result of their use that of a tight bandage with distorting compression of the bones of the toes. Allow me to add that I have no financial or other interest in the firm mentioned above.—I am, etc.,

W. W. SHRUBSHALL, D.P.H.

Work of the R.M.B.F.

SIR,—I am extremely grateful for the most generous response which has been made this year towards our Christmas gift fund. The amount subscribed, £979 3s. 8d., has enabled us to give a Christmas gift of 30s. to every one of our regular beneficiaries.

My thanks are due to you, Sir, for bringing the appeal before your readers, and to all who responded we desire to express our very sincere thanks. The committee is equally indebted to the many secretaries of medical societies, panel committees, hospital staffs, and Divisions and Branches of the British Medical Association who brought the Christmas gift appeal to the notice of their members and who arranged for collections to be made at meetings or donations to be voted. No fewer than 115 cheques from the above-mentioned secretaries, amounting to £511 15s. 8d., have been received.

We are particularly impressed by the spirit of good will and friendship shown towards the work of the Royal

Medical Benevolent Fund in the letters received from many contributors. Practically all "wish every success to the appeal"; others refer to the object of the appeal as "being most deserving." It is clearly shown that it is the desire of members of the medical profession to extend sympathy and practical help through the agency of the Royal Medical Benevolent Fund to those members or their dependants who are living in adversity. The extent to which such help is appreciated may be gathered from this extract from one of many letters of thanks from beneficiaries. The writer is a widow, aged 63, suffering from asthma and bronchitis:

"Will you please give my sincere thanks to the committee for the generous and unlooked-for Christmas gift. It came as a most timely gift. A month ago my doctor ordered me to bed and said that the fire must be kept going night and day, so instead of a 2s. 8d. bag of coal I was able to get a quarter of a ton. I felt it was being very extravagant, and yet on Christmas Eve, after the light was turned out, it was lovely to lie in bed and think of all the blessings one was enjoying through the kindness of unlooked-for friends."

My committee is confident that it is the wish of all that the Royal Medical Benevolent Fund should be worthy of the traditions of our great profession—to be able to give adequate help to those in need. Great advance has been made since the early days and much has been done. We look now to those who have not yet become annual subscribers to join in with us during 1938.

I wish all a happy New Year, and I thank you for the generous co-operation extended by you and your readers to the Royal Medical Benevolent Fund.—I am, etc.,

THOS. BARLOW,
President.

Obituary

R. D. HELM, M.D.

Consulting Physician, Cumberland Infirmary

The death of Dr. Robert Dundas Helm at his residence in Carlisle on January 4 following a short illness has removed a physician with a widespread reputation in the North-West, and one who was, in other respects, a valuable and esteemed member of the community.

A native of Fifehire and born in 1863, Dr. Helm graduated M.B., C.M. of Edinburgh University at the age of 21, and took his M.D. four years later. After graduation he held the appointments of house-physician to the Edinburgh Royal Infirmary and to the Royal Hospital for Sick Children, Edinburgh, and of house-surgeon at the Royal Maternity Hospital, Edinburgh. Following this he came in 1885 to Carlisle as assistant in an extensive county practice. He succeeded to this practice in 1889 and carried it on till the time of his death. In 1896 he was appointed honorary assistant physician to the Cumberland Infirmary, and a year later, on the retirement of Dr. Lockie, he became full physician, serving in this capacity till 1922, when he was appointed consulting physician to that institution. The governors further honoured him by electing him a vice-president. Another institution with which Dr. Helm was long associated and which was dear to his heart was the Border Counties Home for Incurables, Strathclyde House, Carlisle. He served there as honorary physician from 1921, and on the death of Sir Frederick Chance in 1932 he succeeded

will eventually be available for suitably qualified women. It is, however, an interesting commentary on Dr. McCall's complaint that we have recently advertised a vacancy for an honorary paediatrician without receiving a single application from a woman.

Dr. D. E. Barton (January 8) has, I think, read into the article to which he refers a significance which was never intended. I should have hoped that he would welcome the fact that there is not at present—and I hope there never will be—any statutory exclusion of men from our school. This does not mean, as he seems to fear, that the women will gradually be elbowed out to make room for men. But it does mean that there will be the possibility for the ultimate development of a true mixed school with absolute equality for students of both sexes—a type of school which does not exist in London at the present time. There is already an excellent school for women only, but I have gained the impression that there is a keen demand among women of all generations for a mixed school of the type I have indicated. The West London Hospital Medical School is committed to the service of women students, and their interests must naturally come first. But it does not appear that they share the prejudice of men students against co-education in medicine.

The reason why the future "cannot be foreseen" is that we do not know how many women will be applying for admission, nor how long this prejudice of the men will persist.—I am, etc.,

MAURICE E. SHAW,
Dean.

West London Post-Graduate College,
London, W.6, Jan. 8.

Applying for Hospital Posts

SIR,—The letters of "Gamma" (*Journal*, December 25, p. 1305) and others on applying for hospital appointments recall to many of us our own rueful experiences in similar circumstances. The fetish, albeit a lucrative one, of a hospital appointment has introduced methods and morals savouring more of the common gangster than those of a learned and honourable profession. The method of appointment to the staff of certain provincial hospitals has degenerated into what amounts to a racket, and is far worse than any system of fee-splitting so rightly frowned upon by men of honour. Most of the appointments to the junior staff of such provincial hospitals go by favour to the man who has bought himself in, either as a junior partner of some member of the existing staff or by purchasing the practice of such a member. It is common knowledge that professional qualifications and experience count for very little; what matters is a friend at court, and for this the lay members of the hospital committee lay themselves open to influence when it comes to votes. Hospital committees continue the farce of advertising staff appointments and candidates go to trouble and expense to produce testimonials and applications, while all the time some one candidate has been earmarked for the post. Again and again men suitable from every point of view as regards professional and personal qualifications are turned down for some junior partner not half so well qualified. The question arises, What, if anything, can be done to alter a state of affairs so lowering to the profession and harmful to the service of the public? The answer is nothing—unless we care to adopt the only fair and reasonable system of "open" hospitals, such as they have in many parts of Canada. Take, for instance, the General Hospital, Vancouver, which contains about twelve hundred beds and is one of the finest hospitals in the West. It has no honorary staff, and any man on the Medical Register has the right to take his patients into

this hospital and treat them there himself. If he finds the case beyond his powers he calls into consultation one of the specialists he believes in, unlike his British colleague, who has to make his choice from some member of the honorary staff in whom he may not have the slightest confidence. However, in England the system of honorary staffs is so well dug in and so surrounded by the barbed-wire entanglement of vested interest that nothing but the advent of high explosive in the shape of the coming corporate State is likely to break down its smug security.—I am, etc.,

Bournemouth, W., Jan. 5.

VINCENT NORMAN.

Pasteurization of Milk

SIR,—The idea that medical opinion is in favour of pasteurization of all milk is being so cunningly inserted into the mind of the public that I am moved to give you some of our experience. The council to which I have the honour to belong has for years now taken great interest in improving the quality of the milk supply. This it does by taking frequent samples from all the purveyors of milk in the district, and, where a sample is not good, the sanitary inspector takes it up with the producers. The result has been very satisfactory. We have among our producers one by whom the milk is pasteurized. The equipment is absolutely the most modern and the methods used are entirely up to date. Now let me give you an extract from our annual report for 1936.

Pasteurized Milk (Number of bacteria per ml.): Average count, 23,196; lowest count, 60; highest count, 112,000.

<i>B. coli</i> present in 1 ml.	2 samples
" " " 1/10 ml.	2 samples
" " " 1/100 ml.	2 samples
" " " 1/1000 ml.	1 sample

Certified Milk and Tuberculin-tested (Certified Milk): Average count, 9,880; lowest count, 900; highest count, 24,800; *B. coli* absent.

The following is a copy of a report given at our last council meeting. As *B. coli* was present in only one sample of ordinary milk, simply the number of bacteria per millilitre is recorded.

Ordinary Milk Sample No.	Bacteria per ml.	Ordinary Milk Sample No.	Bacteria per ml.
80	56,000	83	49,000
81	72,000	84	61,000
82	48,000	85	25,000
T.T. Milk	Sample 89	45,000
Accredited Milk	" 90	20,000
Sterilized Milk	" 86	27,000
Pasteurized Milk	" 85	25,500
T.T. Certified Milk	" 87	5,000

These results are good and show that pasteurized milk, in spite of all the elaboration and expense entailed in its production, has nothing to boast about. The great need to-day is for an abundant supply of fresh, pure milk at as cheap a price as possible, and I believe that if our Government and local authorities were really determined that the people should have this many difficulties would disappear and a natural supply would become available. Pasteurization is a second best, and may easily become a dangerous second best. We have definite evidence that our certified T.T. milk has produced better results than any other milk. It seems to me very probable that the pasteurization campaign may very easily seriously retard the campaign for pure milk and healthy cattle in this country.

May I add a few notes from our sanitary inspector, Mr. Jump, because we really have gone into this matter pretty thoroughly.

We regret to announce the death at Margate of Dr. WILLIAM WATSON GRIFFIN, who before his retirement practised at Brighton as an ophthalmic surgeon. His medical education was at Otago, New Zealand, and the London Hospital. He graduated M.B., B.Ch. in New Zealand, and held the post of assistant house-surgeon at Dunedin Hospital, later taking his F.R.C.S. in England. He was appointed ophthalmic surgeon to the Royal Sussex County Hospital and also to the Worthing Hospital. He had previously held the posts of senior clinical assistant at the Royal London Ophthalmic Hospital and clinical assistant in the ophthalmic department of the Middlesex Hospital. During the great war he was appointed ophthalmic specialist in the R.A.M.C.(T.), holding the rank of major, and served in that capacity throughout the duration of hostilities. At the Annual Meeting of the Association in Brighton in 1913 he was a vice-president in the Section of Ophthalmology. His fellow practitioners in Brighton have the most pleasant recollections of his work as an eye specialist. He was a colleague on whose opinion they could always rely and unfailingly courteous in all his dealings. It can be said of him that he had a delightful personality, and Brighton doctors will regret the loss of a very distinguished member of our profession.

The following appreciation of Dr. A. COWAN GUTHRIE is by a Glasgow practitioner who acted in consultation with him: From his first days in the study of medicine Guthrie's mind turned to pathology, and after a time in general practice he gave himself up to the study of disease by the specialized methods of laboratory work, bacteriology, histology, and microscopy. He brought to bear on his cases an acute mind in advance of his time, a careful clinical observation, and an originality of thought and action, which made him as a consultant an unusually interesting and helpful guide to both patients and doctors. Those who experienced his attention could not fail to be impressed by the combination of great clinical skill, keen scientific acumen, and freedom from the fetters of convention and tradition that distinguished all his work.

We announce with regret the death of Dr. FREDERICK VAUDREY CANT at the age of 46. Dr. Cant died in the Vaudrey Royal Hospital on January 2 as a result of injuries received in a motor accident on New Year's Eve. He was educated at Cambridge and at the Victoria University, Manchester, taking the Cambridge B.A. in 1912 and going on to the M.R.C.S. and the L.R.C.P. diplomas in 1915. During the war he held a commission in the Royal Army Medical Corps. In 1920, after proceeding to the M.A., he went to Bath, becoming honorary anaesthetist at the Children's Orthopaedic Hospital and senior medical officer to the Ministry of Pensions Hospital. While there he took the D.P.H. at the University of Bristol. He went to Manchester about three years ago, and was appointed chief medical officer to Manchester Collieries Ltd. He had been a member of the British Medical Association for the last twenty years.

Dr. LAWRASON BROWN, resident physician at the Trudeau Sanatorium, Saranac Lake, U.S.A., from 1900 to 1912, died on December 26, 1937, at the age of 66. He had been ill for several months after an attack of pneumonia.

The following well-known foreign medical men have recently died: Professor ERICH LEXER, the master of restorative surgery and director of the Munich University surgical clinic, aged 70; Dr. FERNAND LALESQUE, an eminent physiotherapist and author of numerous works on the treatment of tuberculosis and creator of Arcachon as a health-resort, aged 84; Dr. FERNAND CURTIS, for thirty-five years professor of morbid anatomy at the Lille Faculty of Medicine and author of works on insulin and on cancer, aged 80; and Dr. VAN ROEY, rector of Amsterdam University and professor of gynaecology.

Medico-Legal

A DOCTOR'S DAMAGES FOR LIBEL

Sabapathi v. Huntley

A planter named G. Huntley and his wife had a serious motor-car accident when driving by night in Ceylon. They were taken to a Government hospital, and at once attended and treated by Dr. C. Sabapathi, a senior medical officer of the Government of Ceylon with British and Indian qualifications, who was in charge of the hospital. He visited them next day, and the day after that they left the hospital. Mr. Huntley wrote him a note two days later asking for the accounts, and saying that he and his wife were both very much better and grateful for the way in which they had been looked after. About a week afterwards they consulted a specialist in Colombo, and the x-ray examination made on his advice showed that both patients had fractures. They were accordingly treated in a nursing home. Shortly after entering the home Mr. Huntley wrote to the Director of Medical and Sanitary Services, Colombo, a strong complaint against Dr. Sabapathi for negligence and incompetence, alleging that the doctor, after a very perfunctory examination, had pronounced definitely that no bones were broken, had not suggested an x-ray examination, had actually intimated that the patients might leave on the following morning, and had made no examination of any sort while they were in his hospital except the first examination of two or three minutes, after which he had merely prescribed lead lotion and the usual liniments and had left everything to the acting matron. Mr. Huntley also sent a copy of this letter to the chairman of the Planters' Association, which passed a resolution endorsing its terms. The letter, the discussion, and the resolution were published in several newspapers. Dr. Sabapathi was given no opportunity of explaining or justifying his conduct.

The doctor complained to the Director of Medical Services, and Mr. Huntley said in an interview with the Director that the doctor had examined him and his wife while they were still in the car, and each examination had lasted only half a minute. Dr. Sabapathi then, with the consent of the Government, brought an action for libel and slander against Mr. Huntley. This was tried by the district judge. The doctor gave evidence that he had not examined either patient in the car, but had made a careful and complete examination of both in bed, and had immediately recorded on their bed-head tickets the injuries which he had observed and the opinion "No evidence of fracture." Mr. Huntley, on the contrary, said in evidence that the doctor had examined him and his wife in the car, had felt and moved their arms and assured them that no fractures were present, and when he examined them in the hospital had looked only for cuts and bruises, and had not touched or re-examined their arms and shoulders for fractures. The district judge found in favour of the doctor, accepting his evidence and disbelieving that of Mr. Huntley and his witnesses. He also held that Mr. Huntley's communication to the Planters' Association was not made upon a privileged occasion, and that, if he were wrong in so holding, Mr. Huntley had in making it been actuated by malice so that he could not claim the benefit of privilege. Mr. Huntley appealed to the Supreme Court of Ceylon, who reversed the judge's decision and found in his favour. They agreed that the occasion was not privileged, but found that Mr. Huntley had not made the communication maliciously and that he had proved the truth of his statements.

The Judgment of the Judicial Committee

Dr. Sabapathi then appealed to the Judicial Committee of the Privy Council, who delivered judgment on December 21, 1937. They pointed out the difficulties which hindered Mr. Huntley, like any plaintiff, in proving that he was justified in making his defamatory statements. His first obstacle was to overcome the judgment of the district judge, who saw and heard the witnesses and was thus better able than the Supreme Court to judge of their demeanour and credibility on a pure question of fact: *Powell v. Streatham Manor Nursing*

to the presidency of the institution. When the British Medical Association held its Annual Meeting in Carlisle in 1895 Dr. Helm acted as honorary local general secretary, and at the Edinburgh Meeting in 1898 he was honorary secretary of the Section of Pharmacology and Therapeutics. He was also a past president of the Carlisle Medical Society. During the great war he acted as medical officer in charge of the military hospital at Carlisle Castle. He was appointed a magistrate for Carlisle in 1896, and had been the city's senior magistrate since 1936.

Dr. Helm was a physician of the old school. For many years in Carlisle he had an extensive general practice among the upper classes, and his services were soon widely sought in consulting medicine throughout Cumberland and the neighbouring counties. He had a great natural charm of manner and was friendly and courteous with all, in whatever class, and his passing will be deplored by his many patients and by his colleagues, each one of whom will remember him as a true gentleman in every sense of the word.

EDWARD MAGENNIS, M.D.

Formerly President, Irish Medical Association

Dr. Edward Magennis sen., who represented the Apothecaries Hall of Ireland on the General Medical Council for twenty years and was elected to the Irish Free State Medical Council in 1927, died on January 3 at the age of 82 at his home in Harcourt Street, Dublin. He made a lifelong study of ophthalmology; took a deep interest in public health affairs, especially those relating to the welfare of children in schools; and was the author of books and papers on these subjects.

Edward Magennis was a native of Co. Down, and received his medical education at Queen's College, Belfast, and at King's College, London. He obtained the L.R.C.P. and S.Ed. in 1880, the M.D. of the Royal University of Ireland in 1884, and the D.P.H. of the Irish Royal Colleges in 1891. In early professional life he was for a time clinical assistant at the Royal London Ophthalmic Hospital; then, returning to Ireland, he was appointed ophthalmic and aural surgeon to St. Michael's Hospital, Kingstown. He took the licence of the Apothecaries Hall, Dublin, in 1908 and represented that body on the General Medical Council continuously from 1914 to 1934, and was also for many years a member of its Court of Governors. He had been a justice of the peace for Counties Down and Armagh, president of the Irish Medical Association before its reorganization, and held important positions in other public bodies.

T. K. WHEELER, M.D., M.Ch.

Consulting Surgeon, Royal Victoria Hospital, Belfast

The death on December 29, 1937, of Dr. Thomas Kennedy Wheeler in his ninetieth year has removed from Belfast life a figure who provided a link with past generations, for he obtained his M.D. in the Royal University of Ireland in 1879. The Wheeler family has had an outstanding place in the medical life of Belfast for many generations. The late Dr. Wheeler was the son of a doctor well known and much esteemed by the older inhabitants, and he himself was the father of four doctors. He maintained his faculties until the last, but increasing physical infirmity became manifest during the past few weeks. Even his interest in his beloved pastime of bowls was sustained up to last summer.

Dr. Wheeler had a long, active, busy professional life. His patients were numerous and every one he could consider his friend. He was a member of the surgical staff of the Royal Victoria Hospital, and for some years had been one of its consulting surgeons. A unique record was created some years ago when his son, James R. Wheeler, F.R.C.S., was elected assistant surgeon to the eye and ear department of the hospital, two generations thus holding appointments on the honorary staff. He was also a former surgeon to the Ulster Hospital for Children and Women, and did valuable service there in the surgical department. To his other professional activities were added those of medical officer to the Methodist College, Belfast. In sport he always found a congenial subject of conversation, and in the distinguished place occupied by his sons in Rugby football he took a great pride. His only daughter, Eleanor, who was also a doctor, succumbed to illness some ten years ago, and her death was a blow to her parents, which was borne with a fortitude won from life and experience. Three of his four sons are in the medical profession: Donald R., assistant surgeon to the aural department of the London Hospital; Arthur R., in practice in Wiltshire; and James R., who specializes in ophthalmology in Belfast.

Dr. FLORENCE ROBINSON of Manchester died at her home on December 27, 1937, aged 65. Dr. Robinson received her early education at the Manchester High School for Girls, and since at that time women students were not admitted to the Manchester Medical School she went to the London (Royal Free Hospital) School of Medicine for Women, taking the L.S.A. in 1900 and the London M.B. degree in the following year. After brief periods of residence as house-surgeon in the St. John's Hospital, Lewisham, and the Clapham Maternity Hospital, she returned to Manchester. Together with Dr. Catherine Chisholm she was to a large extent responsible for the foundation of the Babies' Hospital, which has since become the Duchess of York's Hospital for Babies, Burnage, to which she was appointed an honorary physician. Dr. Robinson had been a member of the British Medical Association from 1905 up to her retirement from practice about two years ago.

By the sudden death of Dr. JOHN COWAN WILSON on January 7, at the age of 75, Lanarkshire lost one of its ablest general practitioners who had been a member of the British Medical Association for thirty-two years. He graduated in medicine at Glasgow University in 1883 and took the D.P.H. of Cambridge in 1890. After a short term as house-physician in Greenock Infirmary he started practice in Blantyre, the birthplace of David Livingstone, who would certainly have respected him both for his character and his work. It is not an attractive spot, but there for fifty-three years Wilson gave of his best, and it was a good best—better than most of his patients could readily appreciate, for he kept in close touch with recent developments in medicine and surgery and was himself an excellent surgeon. It was largely due to him that the cottage hospital and the nursing association at Blantyre came into being. His service to the miners and to the poor was as painstaking as to the rich and was never stinted. This was recognized three years ago when the folk of Blantyre celebrated his jubilee among them and publicly honoured him. It was characteristic of him that though he knew he had angina he was at work two days before he died. Always a gentleman, courteous in manner, kind but determined, Cowan Wilson was in the true line of succession to the grand type of family doctor of whom Scotland has had many, and to whom "R. L. S." and "Ian Maclaren" bore witness last century. And, before his polish, he might have sat for the portrait of "The Auld Pairish Doctor" so ably drawn by our contemporary Dr. John F. Fergus. The sympathy of the whole community goes to the widow and her two sons.—J. A.

surgeon on July 27, 1887, became colonel in the long war promotion list of March 1, 1915, and retired on September 10, 1919. He served in the Nile campaign of 1898, when he was present at the battle of Khartum, receiving the medal, also the Egyptian medal with a clasp; and in the war of 1914-18 he was mentioned in dispatches in the *London Gazette* of February 17, 1915, January 4, 1917, and December 24, 1917, and received the C.B.

Colonel T. E. L. BATE, whose military career was briefly recorded in this column on December 18, 1937, studied at Trinity College, Dublin, and shortly after qualifying as a doctor worked for a year as assistant to a general practitioner in Sheffield. On being appointed to the Indian Medical Service he was posted to the Punjab, and shortly afterwards found himself at Peshawar during the progress of the Afghan War of 1879-80. He was later given the post of medical officer to the Lieutenant-Governor of the Punjab, and in that position had opportunities of travelling all over the Province and becoming acquainted with numerous officials and problems outside his own service. Later on he became civil surgeon of Delhi, and from Delhi was transferred to the Provincial headquarters as Inspector-General of Prisons, a post which he held for fourteen years (1891 to 1905). During absences on leave he visited many prisons both in the British Isles and on the Continent, gaining a mastery of his subject which enabled him to introduce many valuable reforms and secured for him in 1902 the C.I.E. After retirement he travelled in various parts of the world, including Canada and South Africa. When the great war broke out he undertook important duties in connexion with Red Cross work in London, and these services were recognized by the conferment in 1918 of the C.B.E.

Colonel DOUGLAS WARDROP, C.B., C.V.O., late R.A.M.C., died at Camberley on December 25, 1937, aged 83. He was born at Barnsburry on February 11, 1854, and was educated at Aberdeen, where he graduated M.B., C.M. in 1875. He entered the Army as surgeon on March 6, 1880, attained the rank of colonel on August 14, 1907, and retired on February 11, 1911. He served as civil surgeon in South Africa in 1879, taking part in the operations against Seku Kuni and in the Zulu War (medal and clasp), and in the Nile campaign in 1898, when he was present at the battle of Khartum, was mentioned in dispatches in the *London Gazette* of September 30, 1898, and received the medal with clasp and the Egyptian medal. From 1902 to 1911 he was commandant of the Royal Army Medical College at Millbank, London, and after retirement he was appointed governor of King Edward VII's Convalescent Home for Officers at Osborne, Isle of Wight. He received the C.V.O. in 1909 and the C.B. in 1917.

Major HERBERT OWEN MARSH BEADNELL, R.A.M.C. (ret.), died in a nursing home at Cardiff on December 15, aged 58. He was born on July 27, 1879, the son of the late Major C. E. Beadnell, R.A., J.P., of Llandinam, and was educated at Guy's Hospital. He took the M.R.C.S.Eng., L.R.C.P.Lond. in 1904, and on July 30 in that year he entered the R.A.M.C. as lieutenant. He became major on July 16, 1916, and retired on April 15, 1919. After the war of 1914-18 he was medical officer in charge of the electrotherapeutic department of the Ministry of Pensions Convalescent Centre at Saltash. He had been a member of the British Medical Association for twenty-five years.

Surgeon Captain ROBERT DUNDONALD JAMESON, C.M.G., R.N. (ret.), died at Fleet, Hants, on January 2. He took the Scottish triple qualification in 1893 and entered the Navy soon afterwards. He attained the rank of surgeon commander on May 10, 1908, and retired with an honorary step of rank as surgeon captain on January 1, 1922. He served throughout the war of 1914-18, receiving the medals, also the C.M.G. and the Legion of Honour, as Chevalier.

Surgeon Captain GEOFFREY CARLISLE, R.N. (ret.), died on January 2. He was the son of the late Paymaster-in-Chief John Carlisle, R.N. He took the M.R.C.S.Eng., L.R.C.P.Lond. in 1904, after which he entered the Navy. He attained the rank of surgeon commander on November 10, 1919, and retired with an honorary step of rank as surgeon captain on September 14, 1928. He served through the war of 1914-18, receiving the medals.

Lieut.-Colonel CHARLES BRIMHALL, R.A.M.C. (ret.), of Warash, Hants, died in London, after a long illness, on December 25, 1937, aged 60. He was born on February 20, 1877, educated at the London Hospital, and took the M.R.C.S. Eng., L.R.C.P.Lond. in 1902. He entered the R.A.M.C. as lieutenant on January 31, 1903, after filling the post of house-

surgeon at Bolingbroke Hospital, and became lieutenant-colonel after the end of the war. He served in the war of 1914-18, and received the Order of Officer of the Crown of Italy in 1920. He joined the British Medical Association in 1922. He served as adjutant in the R.A.M.C., Territorial Force, from November 1, 1911, to July 15, 1915.

Lieut.-Colonel WILLIAM HAMILTON BROWN, R.A.M.C. (ret.), died at Higher Woodway, Teignmouth, on December 26, 1937, aged 83. He was born at Pembrey, Carmarthenshire, on July 19, 1854. His surname was originally Briggs, which he changed to Brown by deed poll dated October 8, 1894. He entered the Army as surgeon on September 20, 1875, was promoted to surgeon major for services in Egypt on June 15, 1885, and retired with a gratuity on November 8, 1890. He was restored to the establishment, and his retirement cancelled, in 1893, promoted to surgeon lieutenant-colonel on September 30, 1893, and retired on December 20, 1893. He served in the Afghan War of 1879-80 (medal) and in the Indian campaign of 1885 (Egyptian medal with clasp and Khedive's bronze star). He was surgeon to the Governor of Madras from November, 1886, to March, 1889.

Lieut.-Colonel JOHN BERESFORD CHRISTIAN, I.M.S. (ret.), died in a nursing home in London on December 31, 1937, aged 64. He was born at Tenterfield, New South Wales, on April 2, 1873, was educated at St. George's Hospital, and took the M.R.C.S.Eng., L.R.C.P.Lond. in 1900. He entered the Indian Medical Service as lieutenant on June 27, 1901, became lieutenant-colonel on December 27, 1920, and retired on June 27, 1928. After eight years' service in the Army he entered civil employ in May, 1909, was again in military employ during the war, from 1914 to 1918, when he rejoined his civil post, and finally reverted to military employ on December 1, 1924. After retiring he settled at Coonoor in the Nilgiri Hills in Southern India.

Universities and Colleges

UNIVERSITY OF LONDON

A course of six public lectures on "Chemical Structure and Pharmacological Action" will be given by Dr. H. R. Ing at University College, Gower Street, W.C., on Mondays, January 17, 24, and 31, and February 7, 14, and 21, at 5 p.m. Mr. H. S. Perera of Colombo will deliver a public lecture on "Phonetics and Psychology" at University College on Wednesday, January 26, at 5.30 p.m. A course of three public lectures on "Surface Chemistry and Biology" will be given by Dr. J. F. Danielli at University College on Mondays, February 28 and March 7 and 14, at 5 p.m. All the above lectures are open to the public without fee or ticket.

Recognition of Teachers

The following have been recognized as teachers of the University in the subjects indicated in parentheses:

Guy's Hospital Medical School: Dr. P. M. F. Bishop (Physiology); Dr. E. R. Boland (Medicine); Mr. K. Hooper, M.R.C.S., L.R.C.P. (Dental Surgery); Dr. A. D. Marston (Anaesthetics); Mr. H. L. Messenger, M.R.C.S., L.R.C.P. (Dental Anatomy); Dr. C. K. Simpson (Forensic Medicine); Mr. T. T. Stamm (Orthopaedics).

Middlesex Hospital Medical School: Mr. P. B. Ascroft (Surgery).
King's College Hospital Medical School: Dr. T. Tennent (Physiological Medicine).

At a meeting of the Senate, held on December 15, 1937, the note in regard to gold medals at the M.D. and M.S. examinations (*Red Book*, 1937-8, pp. 288 and 294; *Blue Book*, September, 1937, pp. 832 and 837) was amended by the addition of the words "or instruments" after the word "books" in the two places in which it occurs.

Dr. A. E. Clark-Kennedy has been appointed Governor of Queen Mary College.

Lectures

A lecture on physiology will be given by Professor A. P. H. de Kleijn of the University of Amsterdam at University College, Gower Street, W.C., on Tuesday, March 15, at 5 p.m.

Professor V. H. Mottam will give a series of ten lectures on dietetics and nutrition at the Kingsway Hall, W.C., on Mondays at 6 p.m., from January 17.

The Services

DEATHS IN THE SERVICES

Home. [1935] A.C. 243. Moreover, Mr. Huntley's statements were antecedently improbable. The evidence showed that Dr. Sabapathi had been in the Government service for twenty-two years, but had never before been accused even of inattention, far less of incompetence and negligence; that members of the Planters' Association were not slow to complain of medical inattention on the smallest provocation; and that Mr. Huntley suggested no motive or explanation at all to account for the negligence he attributed to the doctor. Moreover, the sweeping character of the allegations made them difficult to justify. Lastly, their Lordships said, the plea of justification almost necessarily postulated that the doctor was guilty of perjury and conspiracy, for if Mr. Huntley were right the doctor and his acting matron must be regarded as parties to a plot to bolster up the plaintiff's claim, to deceive the court, and to frustrate the ends of justice. On the other hand, Mr. Huntley was his own main witness, and it was not only charitable but indeed probable to suppose that the accident and shock might have impaired his recollection. He had stated in evidence that he was quite clear on some points and not on others. Their Lordships, in assessing the truthfulness of the evidence, remarked that the Supreme Court of Ceylon had found Mr. Huntley to be wrong in saying that there was an examination in the car and not in the ward, and that if the alleged examination in the car were not only an afterthought but also an untruth, that conclusion cut very deep into Mr. Huntley's case.

They considered the bed-head tickets to be even more significant. These disclosed a course of normal, competent, and careful treatment, and a diagnosis, not of no fracture, but of no signs of fracture—a very different thing. They also disclosed that the doctor visited Mr. and Mrs. Huntley on the morning before they left the hospital—a visit which Mr. Huntley denied.

Duty to Advise X-Ray Examination

The Judicial Committee found it clear that until the x-ray examination was made it had not occurred to Mr. Huntley to make any charge against the doctor. He had actually said in evidence that until the fractures were discovered he had thought the doctor's examination an ample one. The charge which the Supreme Court affirmed against the plaintiff, and upon the affirmation of which they regarded his negligence and incompetence as established, was his failure to advise an x-ray examination. The proposition affirmed by the Supreme Court would seem, said the Judicial Committee, to run thus: after a motor-car accident the attending physician must advise resort to a radiologist, and if he omits to do so he displays both incompetence and negligence. This proposition, said their Lordships, is far too wide. The x-ray examination must always depend on the circumstances, such as the condition of the patient, the character of the injuries, and the accessibility of the apparatus. They thought that Dr. Sabapathi's position had been clear and consistent throughout. He found no evidence of fracture; he allowed the patients to go home, instructing them to let him know how they progressed. If their pain and other symptoms had continued unabated for a week he would no doubt have advised an x-ray examination. When he received the letter saying that they were much better it was not surprising that he concluded that the worst was past. No witness said that to await developments for a week before advising an x-ray examination *per se* constitutes negligence or incompetence in a physician.

Their Lordships therefore found that Mr. Huntley's plea of justification failed. They agreed with both the lower courts that the occasion was not privileged; they agreed with the trial judge that Mr. Huntley was actuated by malice when he wrote the letter, and must have known that its terms were false. They pointed out that the finding of the trial judge on the question of malice was a finding of fact, and saw no reason for disturbing it. The state of a man's mind, they remarked, is as much a fact as the state of his digestion. They thought that the verbal statements made to the Director of Medical Services were made on a privileged occasion, but were not protected because they were made maliciously. They therefore allowed the doctor's appeal, and with it the damages awarded by the trial judge—Rs.10,000.

Surgeon Rear-Admiral Sir DANIEL JOSEPH PATRICK McNABB, K.B.E., C.B., R.N. (retired), died in Deal Hospital on December 25, 1937, aged 75. He was born at Greenock on October 11, 1862, the eldest son of the late Mr. Thomas McNabb of Newcastle-on-Tyne and Southsea. He was educated at St. Cuthbert's College, Ushaw, at Durham University College of Medicine, and at the London Hospital, and took the L.R.C.P. and S.Ed. in 1884, and the M.R.C.S.Eng. in 1886. Entering the Navy in 1886, he became staff surgeon in 1898, fleet surgeon in 1902, and served on the staff of Sir John Jellicoe in 1912. In 1914 he became Deputy Surgeon-General, and was in charge of the transport of Belgian wounded after the fall of Antwerp. For this work he received the Order of Commander of the Crown of Belgium. His rank was changed to Surgeon Captain in 1918. From 1916 to 1919 he was Deputy Director-General of the Medical Department of the Navy, and afterwards was in command of the Royal Naval Hospital at Plymouth, retiring in 1922. He was a naval member of the Medical Consultative Board in 1920. He received the C.B. in 1918 and the K.B.E. in 1919.

Surgeon Rear-Admiral THOMAS TENDRON JEANS, C.M.G., R.N. (ret.), died at Southsea on January 4. He was educated at Manchester, and took the M.B.Lond. in 1893 and the M.R.C.S., L.R.C.P. in the same year. After filling the post of clinical assistant at the Manchester Cancer Hospital he entered the Navy as surgeon in 1894, became staff surgeon in 1902, fleet surgeon in 1910, surgeon captain on June 30, 1922, and retired as surgeon rear-admiral on January 19, 1926. He served in the South African War of 1899-1900, in the Orange Free State (medal), and in the war of 1914-18, serving on the Dardanelles and on the Suez Canal, receiving the medals, and in August, 1919, the C.M.G. During the latter part of the war he was senior medical officer at Portsmouth Barracks, and later in the hospital ship *Soudan*. From 1919 to 1922 he was in charge of the naval hospital at the Cape of Good Hope, and from 1922 to 1926, as surgeon captain, at the head of the naval hospital at Plymouth. He was editor and part-author of *Naval Brigades in the South African War, 1899-1900*. Before the war of 1914-18 he wrote several stories of sea life in the Navy, including *Ford of H.M.S. Vigilant*, *Mr. Midshipman Glover, R.N.*, *On Foreign Service*, or the *Santa Cruz Revolution*, and *John Graham, Sublieutenant, R.N.*, the last being published in 1913. After retirement he published an autobiography, *The Reminiscences of a Naval Surgeon*, in 1927.

Surgeon General THOMAS MAUNSELL, C.B., LL.D., Army Medical Services (ret.), died at Hillingdon Court, Uxbridge, on December 29, 1937, aged 98, probably the oldest member of any of the public medical services. He was born in Dublin on July 1, 1839, the son of Thomas Maunsell, was educated at the Catholic University, Dublin, and took the L.R.C.S.I. in 1859 and the L.R.C.P.I. in 1860. He entered the Army as assistant surgeon on October 1, 1860, was on half-pay from July 24, 1861, to January 14, 1862, attained the rank of surgeon colonel on March 10, 1892, of surgeon general on November 24, 1895, and retired on July 1, 1899. He served in Burma in 1886-7, was mentioned in dispatches G.G.O. No. 864 of 1887, and received the frontier medal; and in the Chitral war on the North-West Frontier of India in 1895 as principal medical officer of the relief expedition, was mentioned in dispatches in the *London Gazette* of November 15, 1895, and received the medal with a clasp and the C.B. In the old regimental days he served in the 48th Foot, now the 1st Battalion of the Northamptonshire Regiment, and in the Royal Artillery. There can be few medical officers left who served in the R.A.M.C. under the regimental system. His university conferred on him the LL.D. He was a founder of the Guild of St. Luke, St. Cosmas and St. Damien, which has already celebrated its silver jubilee. In 1872 he married Mary Eleanor, daughter of the late Major F. W. Lane of the 4th Foot, and had one son and one daughter.

Colonel ANTHONY JOHN LUTHER, C.B., late R.A.M.C., died suddenly at Camberley on December 11, aged 73. He was born at Donnybrook, Co. Dublin, on May 17, 1864, the eldest son of the late Canon Luther of Co. Limerick. He was educated at Trinity College, Dublin, and took the L.R.C.S.I. in 1884 and the L.R.C.P.I. in 1885. He entered the Army

EPIDEMIOLOGICAL NOTES

Typhoid Fever.—At the time of going to press 292 cases have been notified in the Croydon typhoid outbreak with 39 deaths. During the week ended January 8, 1938, there were no new cases but 5 deaths. Of the 24 cases of enteric notified in Northern Ireland 23 occurred at the Antrim Mental Hospital, near Belfast, while one case was reported from Irvinestown. The hospital outbreak is confined to a women's ward which was originally occupied by nearly fifty patients; two of the patients were fairly ill, but the others are progressing well. There have been no deaths. In the borough of Kensington one case of paratyphoid fever occurred in a nurse on the staff of the Princess Beatrice Hospital. The hospital has been placed in quarantine with suspension of admission, while the work of the out-patient department has been transferred to a welfare centre in the vicinity. There has since been one further case.

Dysentery and Infective Enteritis.—In England and Wales the number of cases notified has dropped from 270 to 247 and in Scotland from 58 to 53, but in London itself there is an increase of 5 cases for the week. The numbers notified are greatly in excess of those during the corresponding week last year. The numbers of deaths from enteritis have increased appreciably in the large towns of the British Isles and are about double those for the corresponding week last year.

Measles.—Measles appears to have taken a firm hold in Manchester, where the numbers notified have been rising for the last few weeks. For the week ended January 1, 1938, 707 cases were notified (first case in each household), with 7 deaths, the same number of deaths as in the previous week. In Salford there were 172 cases and 2 deaths, against 1 death for the previous week. The public health authorities have offered a free supply of immune globulin to practitioners in order to secure for measles contacts the benefit of temporary protection or modification of attack. In Edinburgh 174 cases were notified, as compared with 135 in the previous week, while the deaths increased from *nil* to 2. In Belfast the number of deaths from measles has dropped from 6 in the week ended December 25, 1937, to 2 in the week ended January 1, 1938, but the number of cases notified has risen from 292 to 406. The services of additional health visitors have been secured to assist in the domiciliary care of patients with measles. In London the measles epidemic is slowly gathering force. The deaths have risen from 1 in the previous week to 7 during the week under review.

Medical News

The annual meeting of the Royal Microscopical Society will be held at B.M.A. House, Tavistock Square, W.C., on Wednesday, January 19, at 5.30 p.m., when Dr. R. S. Clay will deliver his presidential address on "A Review of the Mechanical Improvements of Microscopes in the Last Forty Years."

The next meeting of the Society of Radiotherapists will be held at 11, Chandos Street, W., on Friday, January 21, when a discussion on "Impressions of the Chicago Congress and of Radiotherapy in America" will be opened by Dr. N. S. Finzi and Dr. J. E. Roberts.

A meeting of the Maternity and Child Welfare Group of the Society of Medical Officers of Health will be held at 11, Thornhaugh Street, W.C., on Friday, January 21, at 8.30 p.m., when a discussion on "Eugenics and Maternity and Child Welfare Work" will be opened by Dr. Stella Churchill. A meeting of the Fever Hospital Medical Service Group will be held at 11, Thornhaugh Street on Friday, January 28, at 4 p.m., when a discussion on "The Prevention and Treatment of the Enteric Diseases" will be opened by Drs. E. W. Goodall and A. Topping.

The Royal Sanitary Institute, in conjunction with the Northern Branch of the Society of Medical Officers of Health, has arranged a discussion on "The National Campaign for Physical Fitness," to take place at Darlington Town Hall on Friday, January 21, at 4.45 p.m. The discussion will be opened by Dr. G. A. Dawson, and will be followed by several short contributions on different aspects of the subject.

A meeting of the Chelsea Clinical Society will be held at Hotel Rembrandt, Thurlow Place, S.W., on Tuesday, January 18, at 8.30 p.m., when Dr. James Davidson, director, Metropolitan Police Laboratory, Hendon, will open a discussion on "The Work of a Forensic Science Laboratory." The meeting will be preceded by dinner at 7.30 p.m.

An address entitled "The Rational and Empirical Elements in Physics" will be given by Mr. H. Dingle on Tuesday, January 18, at 8.15 p.m., at University College, Gower Street, W.C. Cards of admission may be obtained from the Director of Studies at University Hall, 14, Gordon Square, W.C.1.

The following meetings of the Eugenics Society have been arranged: January 18, 5.15 p.m., Dr. G. F. McCleary, "The Population Problems in the British Commonwealth"; February 16, 7.45 p.m., Galton dinner and lecture by Professor John A. Ryle, "Medicine and Eugenics"; March 22, 5.15 p.m., Miss Evelyn Fox, "Modern Developments in Mental Welfare Work"; May 24, 4 p.m., Annual general meeting; 5.15 p.m., Mr. D. V. Glass, "Population Policies in Scandinavia and Elsewhere"; June 14, 5.15 p.m., Miss Grace G. Leybourne, "The Cost of Education and its Relation to the Size of the Family." All the meetings will be held at the Rooms of the Royal Society, Burlington House, W., with the exception of the Galton dinner and lecture at the Waldorf Hotel.

A David Anderson-Berry Gold Medal, together with a sum of money amounting to about £100, will be awarded in July, 1938, by the Royal Society of Edinburgh to the person who, in the opinion of the council, has recently produced the best work on the nature of x rays in their therapeutical effect on human diseases. A similar award will be made every three years. Applications for this prize are invited. They may be based on both published and unpublished work, and should be accompanied by copies of the relevant papers. Applications must be in the hands of the general secretary, Royal Society of Edinburgh, 22, George Street, Edinburgh 2, by June 1, 1938.

According to the recently issued licensing statistics for 1936 the proceedings for drunkenness in 1936 were 52,988, as against 50,032 in 1932 (+5.9 per cent.), 35,407 in 1932 (+49.6 per cent.). The convictions for drunkenness reported as due to drinking methylated spirit were 746 (as against 802 in 1935), of which 634 were in men and 112 in women.

The Treasury has made an Order under Section 10 (5) of the Finance Act, 1926, continuing the exemption of radium compounds from Key Industry duty till August 31, 1938.

Volume XI, No. 1, dated January, 1938, of the *Summary of Current Literature on Water Pollution Research* has just been published by H.M. Stationery Office, price 2s. The annual subscription to these monthly abstracts is 24s., post free. They are prepared by the water pollution research staff of the Department of Scientific and Industrial Research.

According to the *Journal of the American Medical Association* of December 25 statistics from 183 American cities show that there were 14.4 deaths from appendicitis per 100,000 of population during 1936, a slight reduction from the rate of 1935, which was 14.7. The lowest rate on record is 13, which occurred in 1918.

The eleventh International Congress of the History of Medicine will take place from September 3 to 11 in Jugoslavia. The meetings of the congress will be held in Zagreb, Belgrade, Sarajevo, and Ragusa. The following will be the main subjects for discussion: botany and zoology in medicine; the minerals in medicine; medicine in poetry; mysticism and magic in medicine; psychological disorders and psychotherapy in medicine. The president of the congress will be Dr. Lujó Thaller and the secretary-general Dr. Vladimir Bazala. All communications should be addressed to Dr. Bazala, Vaska ulica 95, Zagreb, Jugoslavia.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended January 1, 1938. Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Irish Free State. (e) Northern Ireland. Median values for the last 9 years for (a) and (b).

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 125 great towns (i) in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns (ii) in the Irish Free State. (e) The 10 principal towns (iii) in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1938					1937 (Corresponding Week)					1928-36 (Median Value Corresponding Weeks)

EPITOME OF CURRENT MEDICAL LITERATURE

Medicine

41 Chronic Non-specific Ulcerative Colitis

C. W. MONROE (*Surgery*, October, 1937, p. 575) reviews 138 cases of non-specific ulcerative colitis. The group was made up of seventy-five females and sixty-three males, and in the majority of cases there was definite disease of the colon, in the form of ulceration or bleeding as seen on proctoscopic examination, or narrowing and loss of haustration revealed by x-ray examination. The most common symptom was the passing of blood, pus, or mucus in frequent soft or watery stools. The disease is most often seen in the third decade of life: the average age in Monroe's patients at the onset of symptoms was 30.7 years. Proctoscopic examination showed the rectum to be involved in 82 per cent. of cases, with narrowing of the rectum in eleven instances. X-ray examination showed that the majority of lesions were to be found in or near the sigmoid colon. A table is given showing the multiplicity of organisms found on culture. Emetine was administered in fifty-four cases, to combat a possible amoebic infection. The best results were obtained from acriflavine and bismuth subgallate in mucilage of acacia injected rectally as retention enemas. Vaccines were tried in sixteen cases. Ileostomy was performed in eleven cases, and other surgical measures were carried out in the remaining patients. Blood transfusion was effective early in the disease and was given in nine cases. Complications, particularly those affecting the rectum, were very common. Eleven patients died, spontaneous rupture of the colon with peritonitis being the most common cause of death. The results of treatment show that medical and surgical measures do no more than slow the progress of the disease in the majority of cases.

42 Blood Pressure in Diphtheria

P. v. KISS (*Klin. Wschr.*, October 23, 1937, p. 1493), in a paper based on observations on 404 patients, concludes that in the early stage of diphtheria measurement of the blood pressure is no guide to cardiac or vascular impairment, because the blood pressure during this stage shows an appreciable fall only in complete heart failure, which does not usually set in until twenty-four or at most forty-eight hours before death. A downward tendency of the blood pressure to below 70 mm. Hg is a very unfavourable sign, especially when the pulse frequency is very high or, on the contrary, very low. While severe cardiac disturbances, except in the first three days of the disease, are accompanied by a gradual fall in blood pressure, the hypotension associated with serum sickness is of sudden onset. In the later stage of the disease when the patient is at rest in bed, even in very severe myocarditis, the blood pressure does not fall, but remains normal or rather high.

43 Congenital Tuberculosis

D. PRICE (*Brit. J. Tuberc.*, October, 1937, p. 264) describes a case of congenital tuberculosis. The patient was a child who died aged 49 days; the mother suffered from pulmonary tuberculosis. At necropsy the child's liver and spleen were studded with miliary tubercles. A mass of glands lay round the portal vessels, and a smear from one particularly large gland showed tubercle bacilli. The lungs presented the appearance of bronchopneumonia, and a smear taken from the pneumonic area showed tubercle bacilli. Only one hilar gland was palpable. The congenital origin of the disease is suggested by the size of the portal gland, infection being carried by the maternal blood to the liver. The pulmonary foci might have been mis-

taken for exogenous lesions: but they were recognized as blood-borne by (a) transitional stages between miliary disseminations and large foci, and (b) the condition of the bifurcation gland, which was much smaller than would have been expected in the case of an exogenous lesion. This case shows that not only miliary but also large, solitary, caseous foci can be blood-borne. In contradistinction to this case that of an infant who died at the age of 8 weeks is described. The mother was ill with pulmonary tuberculosis, but nursed the baby for the first two weeks of his life, after which the two were separated. Post-mortem examination revealed a single tuberculous focus at the base of the right lower lobe near the periphery, and the corresponding inferior tracheo-bronchial gland was greatly enlarged. The lung focus showed a more advanced degree of degeneration than did the gland. No other focus was found in the body. Infection probably occurred through inhalation during the first two weeks of life. This case demonstrates the poor degree of resistance of the infant to the tubercle bacillus, death occurring in six or seven weeks' time from the date of infection.

44 Aseptic Meningitis and Anterior Poliomyelitis

J. SIEGL (*Wien. Klin. Wschr.*, October 1, 1937, p. 1357) records the history of a minor epidemic in a kindergarten in Vienna affecting seven children, three of whom suffered from anterior poliomyelitis, while in four the symptoms remained meningeal. He points out that aseptic meningitis and the prodromal stage of poliomyelitis are indistinguishable in their symptomatology, and the changes found in the cerebrospinal fluid are also impossible of distinction. This fact creates immense difficulties in the evaluation of specific therapy. It is impossible to assess whether the absence of paralytic symptoms following the administration of specific serum is due to its effects or to the fact that there had been an aseptic meningitis which would not, in any case, have been followed by paralysis. In two cases of anterior poliomyelitis occurring in uniovular twins, one untreated by specific serum died, whereas the other recovered following the administration of convalescent serum on the second day of his illness. Siegl believes that specific serum can only be of value when given early in those cases of poliomyelitis which have a long prodromal stage. The occurrence of a certain proportion of cases of aseptic meningitis must be borne in mind in epidemics of anterior poliomyelitis.

Surgery

45 Injection Treatment of Varicose Ulcers

S. HANSEN (*Hospitalstidende*, November 9, 1937, p. 13) considers as a great advance the abandonment of extensive operations for varicose veins and ulcers in favour of the injection of coagulants into varicose veins. A Danish study in 1925 of 376 patients operated on for varicose veins or ulcers showed that embolism occurred in twenty-one patients, of whom two died. Though the immediate recovery rate was over 75 per cent., the subsequent relapses were numerous, and most of the patients for whom a cure could be claimed were still obliged to wear bandages. Only twenty out of fifty-three cases of ulceration responded to the operation by recovery. On the other hand, experimental work and clinical observation have both shown that the fear of embolism as a sequel to the injection treatment is much exaggerated, and with an experience of thousands of injections the author has not seen a single case of embolism, let alone a fatal case.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone, unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS should be addressed to the Advertisement Manager. Orders for copies of the *Journal* and communications with reference to subscriptions should be addressed to the Secretary, B.M.A. House, Tavistock Square, W.C.1.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111.

The TELEGRAPHIC ADDRESSES ARE
EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology
Westcent, London.

SECRETARY, Mediœcra Westcent, London.
The address of the B.M.A. Scottish Office is 7, Drumsheugh
Gardens, Edinburgh; tele-
phone 1111, and of the Office of the Irish Free
State is 18, Kildare Street,
Dublin (telegrams: Bacillus, Dublin; telephone 62550 Dublin).

QUERIES AND ANSWERS

Frumenty

A non-medical reader sends the following directions for preparing frumenty in answer to the inquiry published on January 1 (p. 53): Anyone who wishes to make frumenty must first buy a pound of wheat, which costs twopence, from his grocer. All grocers do not sell wheat that is clean enough for this use; many only sell it for cattle and hen food. Run cold water over about half of it on a colander to clean it, and then place the wheat in a baking dish with water to cover it, and as much sugar as is necessary, probably one or two tablespoonfuls, and a little nutmeg and a saltspoonful of salt. It needs a great deal of stewing. Even two days in a slow oven is not too much; but at any rate one day, in a moderate oven—that is, so that it simmers all the time—is necessary. It is best covered with a plate to keep it moist. These are the instructions I had from a countrywoman, and I have tested them. The wheat swells and absorbs the water, but it should have more water put in while it is cooking, not allowed to go dry until the end. It must become soft and rather jelly-like. Frumenty ought to be good for the teeth, as it needs a good deal of chewing. It is a "Wakes Week" dish in some Lancashire towns.

Dr. SEYMOUR W. DAVIES (Wallasey, Cheshire) writes: About fifty years ago frumenty (or furmetty, as we called it) was often served in our family at breakfast as a change from porridge, and we all liked it. It was made in the following way. Wheat, in a stone jar, is covered with water, allowing for expansion, which is considerable when the wheat swells. The jar is put in the oven and stewed gently for hours, until the grains have burst and have absorbed the water, leaving a soft mash. A tablespoonful or so of the mash is put into a pint basin, covered with plain white sauce, syrup added, the whole stirred well, and eaten with a spoon. We like a dash of powdered cinnamon. An excellent meal, but rather troublesome to prepare in these degenerate days of pre-cooked cereals.

Herpes and Varicella

Mr. L. A. RIDDELL, F.R.C.S. (Redruth), writes in reply to Dr. I. H. Lloyd-Williams (*Journal*, January 1, p. 54): One might almost say that herpes zoster is endemic in Cornwall, so common is it here. From time to time one certainly does see "chicken-pox in the little girl and grannie with zoster"; but with the majority of cases of either of the two diseases no such association is found. Moreover, varicella attacks healthy children, whereas I fancy that zoster prefers the debilitated, though it is difficult to separate cause and effect. To my mind the greatest argument against the identity of the two is the fact that varicella commonly

causes nothing but a little skin irritation, whereas zoster, even when it occurs in a child, nearly always causes severe pain as well, at least in the early stages. If they are caused by the same virus, then in chicken-pox it must be confined to the skin, while in zoster it must (as is usually believed) affect the cutaneous nerves directly. This is not difficult to believe seeing that both are ectodermal structures. But in this case, is the primary lesion in the dorsal root ganglia, as I believe I was taught?

Income Tax

Partnership Assessments

"L. s. d." has sent inquiries the purport of which will be clear from the replies below.

** (1) The income tax assessment is made on the firm as such and not on the individual partners, and the collector's receipt for the tax when paid is given accordingly, and a partner cannot claim to have an official receipt for his share of the firm's tax.

(2) The return or declaration of income, however, is made by each partner separately, including therein his share of the firm's liability, which should agree with the return made by the precedent acting partner stating the firm's liability.

(3) The official notice of assessment shows the personal allowances and reliefs aggregated, but the inspector of taxes will supply an individual partner on request with a note stating what he is personally entitled to and what is accordingly included in his account in the official notice.

LETTERS, NOTES, ETC.

Hire and Supply of Gas Apparatus

"GASSED" (London, W.9) writes: I would like to know the opinion of the profession on the hire and supply of gas and oxygen; also whether a less arbitrary form of charge would not be more satisfactory. I have recently had the following experience with a large supply firm. I hired a gas and an oxygen cylinder on the understanding that I paid for what I used in the first six months, afterwards at the rate of 6d. each cylinder a week. At the end of six months I returned the cylinders, and was charged 3s. for the gas and 2s. 4d. for oxygen. What I had actually used was one fill of the gas bag to my Clover apparatus and no oxygen at all. The firm state the valves were in perfect order, and I certainly saw the gas tap was off and tight after use. So that the whole affair is most unsatisfactory, which gives no encouragement to keep gas or oxygen in the house for emergencies. It would probably be better to pay a small hire charge from the start.

The Bicentenary of Parmentier

The *Canadian Pharmaceutical Journal* for December 15, 1917, includes an annotation on the French pharmacist, Antoine-Auguste Parmentier (1737-1813), who made France "potato-minded." While a prisoner of war in Germany—he had joined the French Army Pharmaceutical Service in Harcourt in 1757—he learnt to recognize the merits of the potato, then his chief article of diet. Returning to Paris, as *pharmacien-adjoint* at the Hôtel des Invalides, against popular indifference and prejudice he introduced the potato into every restaurant menu and was responsible for the cultivation of the plant on an extensive scale. To encourage him Louis XVI wore a sprig of potato leaves in his button-hole. In 1800, under Napoleon, Parmentier became general of the sanitary corps, and later prepared a pharmacopœia code, which was adopted by many hospitals. His publications are numerous and interesting, but betray the lack of a sound academic training in his early days. His hundredth anniversary was recently celebrated in his birth town, Montdidier, by a gastronomic pilgrimage to the house where he was born (the house itself was destroyed during the war of 1914-18) and by other ceremonies in which potatoes had a place of honour.

Vaccines and Sera

We have received from British Drug Houses, Ltd., Goshop Street, City Road, London, N.1, a booklet entitled *Vaccines and Sera*. Short notes are given on the preparation of employing various vaccines and sera, and a price list is included at the end of the booklet, which may be sent free to anyone who cares to apply.

Radiology

51 Effect of Thorotrast on Liver and Spleen

E. L. LANARI, M. E. JORG, and J. A. AGUIRRE (*Presse méd.*, November 6, 1937, p. 1562) condemn the use of thorotrast for the purpose of radiological investigation. They have been able to prove by experiments spread over a period of four years that thorotrast produces a combination of marked degenerative and regenerative changes in the liver and spleen, where the thorotrast is retained indefinitely in the reticulo-endothelial cells. They ascribe the effects partly to the radio-activity of thorotrast. The changes ultimately result in a slowly progressive cirrhosis of the liver and in a hyperplasia and fibrosis of the spleen. Ultimately other viscera, such as the kidneys, may be secondarily affected.

52 X-Ray Sickness

W. D. GERMAR (*Med. Welt*, November 20, 1937, p. 1642) discusses briefly the nature, symptoms, and mechanism of x-ray sickness. Exposure to sunlight after intensive x-ray treatment seems to aggravate the condition. The patients must therefore be protected against sunlight during the course of treatment. The different remedies suggested for x-ray sickness, such as cardiazol-ephedrin, sympatol, ephetonin, sea-sickness remedies, glucose, etc., have all proved of limited usefulness. The author has treated successfully one hundred cases of x-ray sickness with a liver preparation—hepatrat. In mild cases the patients received an intramuscular injection of 1 to 2 c.cm. of this preparation: the injection was repeated after one hour whenever necessary. In severe cases 5 c.cm. were injected at once.

53 Irradiation of the Pituitary

R. ZOLLINGER and W. W. VAUGHAN (*New Engl. J. Med.*, August, 5, 1937, p. 219) state that optimistic reports of the value of irradiation of the pituitary gland in the treatment of menopausal symptoms led them to use it in fourteen women. In two of these the menopause was of natural occurrence, in seven it followed castration, in four after x-ray therapy, and in one after the application of radium. A total of 1,600 r skin doses was given over a period of four days. The criterion of success or failure of the treatment was based on an accurate recording of the number of "hot flushes" experienced daily before and after it. Improvement occurred in only 35 per cent. of the authors' cases. Sham treatments to avoid psychic effect were unattended by improvement. Treatment appeared to have no effect on the basal metabolism, sugar tolerance curves, or the vaginal mucous membrane. The authors state that at present there is no method of determining beforehand which patients suffering from menopausal symptoms will benefit by irradiation of the pituitary.

54 L. DELHERM and H. FISCHGOLD (*Bull. Soc. Radiol. méd.*, Paris, October, 1937, p. 611) believe that certain cases of insulin-resistant diabetes can be influenced by irradiation of the pituitary. They assume that diabetes is a polyglandular disturbance and that irradiation of the hypophysis may be useful only in so far as this gland is involved in the endocrine disturbance. The pituitary seems to secrete a hormone which normally counteracts the pancreatic hormone. It is possible to depress this particular hormone by irradiating the pituitary with fairly large doses of x rays. The authors define the term "insulin-resistance" and cite two clinical cases in which irradiation of the pituitary had a markedly beneficial effect. There was no cure of the diabetes in either of these cases, but whereas before the irradiation very large doses of insulin had hardly any effect, after the

irradiation it was possible to reduce the doses of insulin to the usual level. The x-ray dosage varies according to the clinical course. In one case it was necessary to administer to the pituitary 12,000 r units within a year; in another case a dose of 3,600 r units had an immediate beneficial effect.

55 Tumour-like Shadows in Silicosis

M. CONROZIER and J. MAGNIN (*J. Radiol. Électrol.*, October, 1937, p. 433) describe thirty cases of silicosis of the lungs in which the pulmonary infiltration appeared as solid tumour-like masses, surrounded by clear, though more or less fibrosed, pulmonary parenchyma; the masses were usually not connected with the hila or with the thoracic walls. The shadows were mostly bilateral, but the right lung was usually more affected than the left. The shadows resemble sarcomatous metastases, but the latter are more rounded and the parenchyma which surrounds them is not sclerosed, as in silicosis. The authors believe that the shadows are caused by fibrotic tissues impregnated with silica. Some of the affected patients remained comfortable for about twenty-five years, but one-half of the patients under observation died within eight years. It seems that heavy dusts with a high content of silica are responsible for the tumour-like infiltration. Miners working underground are particularly prone to develop such massive infiltrations. Clinically the patients appeared healthy. They were apyretic: and auscultation alone revealed nothing abnormal in the chest. As a rule the heart remained unaffected, but dyspnoea was always pronounced. The sputum only rarely contained tubercle bacilli.

56 Diagnosis and Treatment of Syringomyelia

E. B. GUREVITCH, G. B. FOMIN, and P. B. SHKLOVSKAIA (*Amer. J. Roentgen.*, September, 1937, p. 415) describe the radiographic changes in bones and joints met with in syringomyelia and record the results of x-ray therapy in 137 cases of this disease. The most common change in the bones was an overgrowth of the distal phalanges. This was seen in 24.4 per cent. of cases; amputation of distal phalanges was met with in 16 per cent. The different joints were unequally affected, the most commonly affected being the phalangeal articulations (12.8 per cent.), and next to them came the wrist and elbow, each affected in 9.6 per cent. of cases. The authors used deep x-ray therapy and obtained good results from this treatment in 69 per cent. of cases. One case was made worse by the treatment, while 31 per cent. remained uninfluenced. In the successfully treated cases the sensation of pain was the first to return; next came the thermal sense, although in some instances the first improvement was in the motor disturbances. The authors do not believe that old-standing cases remain refractory to the treatment. As to the *modus operandi* of x-ray therapy in syringomyelia, they share the opinion of most workers that the x rays attack directly the glial hyperplasia; the nerve tissue is thus released from pressure.

Obstetrics and Gynaecology

57 Treatment of Abortion

F. HOLTZ (*Hygiea*, Stockh., October 31, 1937, p. 737) finds that opinions still differ as to what is the best treatment for abortion, and he has therefore attempted to clarify this subject by an investigation of the cases of abortion-treated in various Swedish hospitals in 1928 to 1930. During this period 2,718 abortions were dealt with on several different lines, the patients' ages ranging from 15 to 47. After an observation period of at least four

During the past three or four years, using as a coagulant a solution of sugar, he has not seen a single case of necrosis at the site of injection. The author's own experience is that, although objective signs of relapse are demonstrable in about 50 per cent. of cases from one to five years after injection treatment, the formation of new varicose veins does not necessarily imply subjective disturbances. Indeed, about 85 per cent. of the author's patients were symptom-free after an observation period of one to five years, and they still found bandages superfluous.

46

Pituitary Implantation

E. KYLIN (*Med. Klinik*, November 5, 1937, p. 1497) has now implanted an animal pituitary into the mesentery or peritoneum in sixty patients—including thirty-eight cases of Simmond's disease or "its subgroup, cachexia of late puberty," three of dystrophia adiposogenitalis, three of hypophyseal dwarfism, five of total alopecia, and six of psoriasis. The therapeutic effects described are superior to those attained similarly by others; Kylin attributes this to his technique, by which small pieces of a calf's pituitary, without having been frozen, are sutured in place within thirty to sixty minutes of the animal's slaughter. Many cases are too recent for assessment of results, but ten patients with Simmond's disease have had implantations done eighteen months or more ago. Six are working, one is improved, two have died of intercurrent disease, and one only has suffered recurrence. Lasting returns of menstruation and very great increases of weight have been noted. In total alopecia one case is very recent, and there have been three successes with one failure. Pituitary implantation was tried in psoriasis because this was regarded as due to an endocrine disturbance of fat-metabolism, and the gland is now known to secrete a fat-splitting hormone; five successes in six cases are recorded. Discounting the possibility that the good results are due to suggestion, Kylin holds that either (1) the implant functions as a transitory depot of the hypophyseal hormones which stimulate other endocrine glands or (2) it acquires vital connexions and continues to function—for which some evidence is forthcoming from investigations by the author and by Hill and Gardner, who proved survival for 120 days of mouse-to-mouse pituitary implants.

47

Regional Ileitis

P. VALDONI (*Policlinico, Sez. Chir.*, November 15, 1937, p. 595) records three cases of regional ileitis, two of which occurred in women, both aged 28; the other was in a man, aged 25. Two of the cases resembled each other in their previous history of intermittent attacks of abdominal pain and in their onset, simulating appendicitis, for which laparotomy was performed. In the first case drainage only was carried out, while in the second the appendix was removed, and a few days later a faecal fistula developed; a fistula between the caecum and small intestine was also discovered. The third case was a chronic form of regional ileitis, in which recovery followed resection of the caecum, ascending colon, and lower end of the ileum and the formation of an anastomosis between the ileum and transverse colon.

48

Hernia of Nucleus Pulposus

A. RUBINO (*Riv. Neurol.*, October, 1937, p. 491) describes a case of hernia of the nucleus pulposus of the fourth lumbar vertebra, which was diagnosed clinically and confirmed by x-ray examination. The patient was a man of 53 who, while lifting a heavy weight from a stooping position, suddenly felt a lancinating pain in the lumbar region so intense that he was unable to raise himself for several minutes. For three months he was unable to straighten his back or lift himself up in bed, and even two

months later the pain, though less severe, was still present, and was made worse by walking or by bending backwards or forwards. He also complained of paraesthesiae in the lower limbs and at times of pain along the course of the sciatic nerves. On examination nothing abnormal was discovered apart from tenderness on percussion over the spine of the fourth lumbar vertebra and a certain amount of rigidity of the trunk owing to limitation of flexion and extension of the lumbar spine on account of pain. In view of the history, the absence of any other positive findings, and the circumscribed area of pain and tenderness, the possibility of a hernia of the nucleus pulposus was at once considered. A radiograph taken two and a half months after the injury had shown only an early arthritis deformans limited to the third and fourth lumbar vertebrae, but later radiographs revealed an irregular circumscribed shadow on the superior aspect of the fourth lumbar vertebra near its posterior border, and apparently forming a hollow in the body of the vertebra. The author discusses at length the aetiology, pathogenesis, and symptomatology of hernia of the nucleus pulposus in its two forms of "Schmorl's intravertebral and Schmorl's intrarachidian nodules."

Therapeutics

49 Leukaemic Blood for Agranulocytosis

T. DEGLMANN (*Dtsch. med. Wschr.*, November 5, 1937, p. 1694) was encouraged by Bock's recent experience in the treatment of agranulocytosis with the transfusion of blood from a case of myeloid leukaemia to repeat this experiment in an apparently desperate case of his own. His patient was a woman, aged 28, who on admission to hospital was partially unconscious and suffering from the high fever and a progressive necrotic stomatitis. The clinical diagnosis of agranulocytosis was confirmed by a blood count, which showed only 1,200 leucocytes per c.mm. There were no granulocytes, monocytes, or eosinophils, and only a few lymphocytes. The prognosis being very bad, 500 c.cm. of blood were transfused from a man, aged 39, who suffered from myeloid leukaemia and belonged to the same group as the recipient of his blood, which showed 200,000 leucocytes per c.mm. The transfusion was well tolerated except for an attack of shivering, and it was repeated after a short interval. 500 c.cm. being again injected, this time without any reaction. The leukaemic donor was compensated for the loss of blood by a transfusion of normal blood from the patient's mother. The author is inclined to attribute the patient's recovery to the receipt of 1,000 c.cm. of leukaemic blood of which the leucocyte content was equivalent to that of 40 litres of normal blood.

50

Lupus Erythematosus

According to H. T. SCHREUS and E. SCHWITZ (*Med. Klinik*, November 26, 1937, p. 1597) the results of gold and of bismuth treatment in lupus erythematosus are about equally good, giving cure in 32 to 42 per cent. of cases and improvement in 25 to 42 per cent. Bismuth, however, should be given the first trial, since it is less liable to induce toxic symptoms, manifested by nephritis, exanthemata, or stomatitis, or to reactivate latent tuberculous foci. They report twenty-two in-patient cases treated by bismogenol injections: of these, eleven were cured and the rest improved. The cases cured included eight of five to twenty years' duration. Two or three courses of fifteen injections of 1 c.cm. were required in more than half the patients; occasionally the treatment was combined with the application of carbon dioxide snow or irradiation therapy.

Effective VACCINE THERAPY

without untoward reaction...

THE high standard and rapidity of the immunity response from Dissolved Vaccines G.L. are due to two factors: first, that the organisms, being in solution, are available for antibody production immediately upon injection; second, that being detoxicated, the vaccines can be given in adequate dosage without producing unfavourable reactions.

PRICES: Whooping Cough Dissolved Vaccine G.L.; 5 cc. bottles, 10 9; 10 cc., 15 6; 25 cc., 25 -. Gonococcus Intradermal Dissolved Vaccine G.L.; 3 cc. phials, 6 8. All others; 5 cc., 7 6; 10 cc., 10 9; 25 cc., 17 6. Subject to usual professional discount.

TREATMENT of the COMMON COLD
Injection of the Cold Dissolved Vaccine G.L. has achieved conspicuous success in treatment. One or two doses ($\frac{1}{2}$ to 1 cc.) administered in the early stages of a cold will, in the majority of cases, bring about a rapid regression and termination of the symptoms.

GLAXO LABORATORIES LTD

GREENFORD, MIDDLESEX. BYRON 3434

years information was obtained from, or about, 1,370 patients. As many as 901 refused to give any information. It was found that 440—that is, about one-third of the patients traced and reported on—had succeeded in avoiding subsequent pregnancies, and just over half (52.6 per cent.) of those who gave information on this score associated the avoidance of pregnancy with coitus interruptus, whereas only 21 per cent. had achieved the same end by abstinence. In about one-quarter of the cases in which the influence of abortion on libido was investigated it was said to have been reduced since the abortion. In this matter age would seem to play an important part, the older the patient the greater the frequency with which abortion was followed by a diminution of libido. As for the best treatment of uncomplicated abortions to be adopted early in pregnancy, the author favours active intervention unless there is convincing evidence of the abortion having already been complete. He also recommends active intervention in abortions late in pregnancy, but only when the placenta is retained. In all other uncomplicated abortions late in pregnancy he recommends conservative treatment. For complicated abortions at all stages of pregnancy he recommends conservative treatment, the only contraindication to which is severe haemorrhage.

58 Curettage for Endometrial Hyperplasia

K. H. KÖSTER (*Hospitalstidende*, October 19, 1937, p. 1164) remarks that it may seem irrational to curette for the relief of irregular glandular hyperplasia of the endometrium, considering that its origin is now thought to be ovarian rather than uterine. Yet even if such treatment is only symptomatic, its practice may be justifiable if the good results are frequent and lasting. To throw light on these questions the author has investigated the subsequent fate of 135 patients for whom curetting was prescribed once or oftener for hyperplasia of the endometrium, between 1918 and 1936 in the gynaecological department of a Danish hospital. The curetting was followed by intra-uterine irrigation or painting with iodine. Nearly all the patients were between the ages of 30 and 50, only eleven being under 30 and fourteen over 50. Among the patients between 45 and 50 there were ten who were insane. As many as 101 had been confined once or oftener, and it would seem, judging from this study, that multiparae are more liable to develop hyperplasia of the endometrium than nulliparae or uniparae. The excessive uterine haemorrhage had in most cases followed a stage of amenorrhoea. After discarding from the analysis those patients in whom the issue had been confused by supplementary treatment with radium, x rays, etc., there remained 120 for whose intra-uterine condition only curetting had been performed. In thirty-two of these cases regular and normal menstruation was restored. One patient was subsequently irregular in her menstruation and became pregnant. There were also fifteen patients in whom the haemorrhage ceased altogether. A recurrence of the haemorrhage had to be recorded in as many as seventy-two cases. It would therefore seem that the restoration of normal menstruation or the complete cessation of any uterine haemorrhage may be anticipated in about 40 per cent. of cases as a result of curetting, once or oftener.

59 Scalp Forceps

E. SCHEHL (*Zbl. Gynäk.*, October 23, 1937, p. 2504) states that since 1931, at the Würzburg University clinic, for accelerated delivery in placenta praevia reliance has been placed (in case of failure of rupture of the membranes) on traction on the foetal head by serrated forceps grasping the scalp. This method seldom fails, and has been found preferable, in vaginal delivery, to version and traction by weight on a foot, as formerly used in these cases; it is simple, and reduces both the danger of maternal infection

and also the high foetal mortality—the latter by 66 per cent. Schehl warmly commends the method, and does not confine it to hospital practice. H. PANNKE (*ibid.*, p. 2508) uses a weight of 500 grammes only, and records successful application of the scalp forceps for the purpose of inducing labour in twenty cases in which medical measures had failed. Strong pains follow at once, and the average duration of application is six hours. The authors agree that no serious injury of the foetal scalp is produced.

Pathology

60 Hormonal Regulation of Red Blood Cells

W. JULIUS and F. MEYTHALER (*Folia Haemat.*, Lpz., 1937, 57; 4, 389) draw attention to the part played by various hormones in the regulation of the erythrocytes. An increase of erythrocytes in the blood up to 100 per cent. follows rapidly on the injection of adrenalin either subcutaneously or intravenously; it may persist for twenty-four hours. The amount of haemoglobin is not affected. This is not due to a specific hormonal effect on the erythropoietic system, but to a flooding out of the blood deposits in the body, notably the spleen. Thyroidin has the same action. In a patient with Graves's disease and polycythaemia the erythrocyte count was lowered from 14 millions to 7 millions following x-ray therapy, but rose to 15 millions on the administration of 0.1 gramme thyroidin. The occurrence of anaemia with hypofunction and polycythaemia with hyperfunction of the genital glands has been recorded in the literature. The authors believe that clinically and experimentally it has been proved that blood diseases may occur as the result of hormonal disturbances, and that hormones produce a physiological regulation of the circulating blood. In a series of experiments on healthy persons, diabetics, and patients suffering from hyperthyroidism, both in the fasting and non-fasting state, they were able to show that parallel oscillations of the blood sugar and erythrocyte count curves took place following the injection of insulin and the antagonistically released adrenaline.

61 Interrelationship of Liver and Spleen

B. HERHAUS (*Münch. med. Wschr.*, November 12, 1937, p. 1807) believes that the liver and spleen form a unit in the body not only as members of the reticulo-endothelial system but in their interdependence in carbohydrate metabolism, in their formation of bile pigments and salts, and in the metabolism of cholesterol and purine bodies. He describes in detail a case of haemolytic icterus which cleared up following splenectomy but in which a hepatic icterus occurred a few months later. Herhaus explains the hepatic icterus by assuming that splenectomy may produce a serious disturbance of the liver-spleen interdependence. The liver is flooded with fragile erythrocytes, which go on being formed in the bone marrow as before, and indeed are increased in number following splenectomy. Bilirubin is produced which appears in the urine. When the need for erythrocytes is less than the output of them by the bone marrow the liver cells are damaged owing to the imperfect excretion from them of bilirubin. Herhaus believes that the liver-spleen interdependence is disturbed in the so-called splenic crises, which are attended by anaemia, increase in size of the liver and spleen, hepatic pain, and the appearance of bilirubin in the urine. These crises have been thought to be due to collapse of the bone marrow, but against this is the fact that the blood picture is that of regeneration with an increase of embryonic cells in the blood. The crises are probably a result of sudden temporary cessation of splenic function.

DESOUTTER

CASE RECORDS

Case No. H2029. 1934

Mrs. B., a patient with a left Syme's amputation, came to see us in 1934 with an appliance that she had been wearing for two years which was ugly, heavy and ill-fitting, and causing her great discomfort. As a result of incorrect alignment the steel supports had caused pressure sores to develop at the inner side of the knee and outer end of the stump.

The end bearing, which should be the great asset of Syme's amputation, was taking practically no weight, by far the greater part of the weight being taken on a thigh corset with a bearing on the ischial tuberosity. Yet, in spite of this, the end pad of the stump was already showing signs of loosening due to the outward lateral movement which took place at every step (see Figure 1). If such end results are obtained, it is small wonder that many surgeons may regard Syme's amputation as unsatisfactory. In point of fact a Syme's can be as satisfactory an amputation as any other, when correctly fitted, as the case in question shows.

A plaster cast of the stump was taken, the positive copy of which was suitably modified to make use of the weight bearing points under the knee, and to ensure that the end bearing pad could expand without friction whilst taking a full share of weight. A leather glove was then moulded to the cast (see Figure 2) and encased in a light metal shin with a thin stainless steel cup forming the end bearing, giving great strength combined with lightness and a smooth outline, the mechanism for the ankle movement being a self-contained unit under the end bearing.

Owing to the fact that the lower end of a Syme's amputation is much larger than the leg above it, it is only necessary to allow the lower end of the leather glove to open; the fastenings to the metal shin are quick and simple and so firm that once the limb is on it cannot be pulled off. The result is a comfortable light limb of neat appearance (this of no small importance to a woman), taking the weight on the end bearing and below the knee (see Figure 3).

CURTIS - *The Support* *that is prescribed by leading* **London Hospitals**

The Curtis Abdominal Model No. 1 is the best method of supporting the lower abdomen without undue constriction. It is scientifically designed to give an even anterior-posterior pressure—at the same time allowing greater freedom to the hips. Model No. 1 is indicated in the treatment of all forms of abdominal ptosis-visceroptosis, enteroptosis and gastropptosis; and it is recommended for support of ventral hernia and scar tissue in the lower abdomen.

THE SWEDISH NATURAL TABLE WATER

—a natural alkaline water of tonic properties, used extensively by athletes and invalids in Sweden.

Supplied by Special Warrant to
H.M. the King and H.R.H. the
Crown Prince of Sweden, and also
to H.M. the King of Denmark.

RAMLÖSA

50 YEARS' REPUTATION FOR MEDICINAL AND TABLE USE

This famous natural mineral water is bottled at the source and slightly aerated with pure Carbonic Acid. The characteristics of "Ramlösa" are a relatively high Sodium Carbonate content in combination with an uncommonly low content of Calcium and Magnesium Salts (practically no lime) and a virtually complete absence of iron. "Ramlösa," in consequence, avoids the fault of certain natural mineral waters which upset the digestion by partially neutralising the hydrochloric acid in the gastric juice. "Ramlösa" considerably increases the amount of urine and is therefore indicated in the treatment of diabetes, gout, kidney troubles and other metabolic disorders, as well as in rheumatism and in conditions where a large supply of fluid is of importance as a mild form of irritant physical therapy.

TWENTY-FIVE per cent. **HōVIS**
of the flour from which the
loaf is produced is wheat germ

Science advocates the use of germ-bread as a factor in promoting nutrition. That is why HōVIS figures so prominently upon the dietary when the question of food value must be studied. In white bread, the wheat-germ is practically nonexistent. This vitalising source of protein, fats and phosphates abounds in HōVIS. In fact, twenty-five per cent of the flour from which the HōVIS loaf is produced, is WHEAT-GERM. Apart from its low starch-content, HōVIS is practically free from bran and indigestible cellulose. This fact makes HōVIS supreme for easy digestibility and assimilation.

CVS

De KUYPER'S HOLLANDS

Distilled with the Juniper berry from genuine malt liquor. The advantage gained by distilling the berry with the spirit is the production of a preparation of Oleum Juniperi, mellow and free from all irritating properties.

It can be described as carminative, anti-spasmodic and a stimulating diuretic, valuable in many conditions and can be safely taken with regularity

*Distilled by the same
family for 241 years*

THE RESIDENTIAL TREATMENT OF ALCOHOLIC & DRUG ADDICTION

RENDLESHAM HALL

(Postal Address) — **WOODBIDGE, SUFFOLK**

Rendlesham Hall, which is open to receive patients, is essentially a Sanatorium. Its daily life and routine are that of an ordinary comfortable holiday or health resort, or of a large country house. Each patient has all the privileges of a guest consistent with the prescribed medical treatment.

RENDLESHAM HALL—SOUTH VIEW

Rendlesham Hall has 45 bedrooms and about 450 acres of gardens and park. It has also a private nine-hole golf course, tennis and croquet lawns, and bowling green.

Illustrated booklet giving particulars as to terms, etc., can be had on application to the
RESIDENT MEDICAL SUPERINTENDENT.

Telegrams and Telephone: WICKHAM MARKET 16. (Toll Call from London.)

Proprietors: The Norwood Sanatorium, Limited.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY

President: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., A.D.C.

This registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary patients, who are suffering from incipient mental disorders or wish to prevent recurrent attacks of mental trouble, temporary patients, and certified patients of both sexes, are received for treatment. Careful clinical, biochemical, bacteriological, and pathological examinations. Private rooms, with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

WANTAGE HOUSE

This is a Reception Hospital in detached grounds with a separate entrance, to which patients can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical bath, Plombières treatment, etc. There is an Operating Theatre, a Dental Surgery, an X-ray room, an Ultra-Violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for biochemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit, and vegetables are supplied to the Hospital from the farm, gardens, and orchards of Moulton Park. Occupational Therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The seaside house of St. Andrew's Hospital is beautifully situated in a park of 330 acres. Llanfairfechan, amidst the finest scenery in North Wales. On the North-West side of the Estate, a mile of sea coast forms the boundary. Patients may visit this Branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard courts), croquet grounds, golf courses, and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts, such as carpentry, etc. For terms and further particulars apply to the Medical Superintendent (Telephone Nos. 2356 and 2357 Northampton), who can be seen in London by appointment.

COURT HALL, KENTON, near EXETER,

for the treatment of eight Ladies, voluntary, temporary, or certified patients.
Large gardens and own dairy.

CLIFFDEN, TEIGNMOUTH, for early and convalescent cases. A well-appointed house, with spacious balconies, and extensive views of the South Devon coast. Sub-tropical gardens, own dairy in 25 acres. Private road to beach.
